Rosemount™ 389/389VP

General Purpose pH/ORP Sensors
Essential Instructions

Read this page before proceeding!

Emerson designs, manufactures, and tests its products to meet many national and international standards. Because these instruments are sophisticated technical products, you must properly install, use, and maintain them to ensure they continue to operate within their normal specifications. The following instructions must be adhered to and integrated into your safety program when installing, using, and maintaining Emerson products. Failure to follow the proper instructions may cause any one of the following situations to occur: loss of life, personal injury, property damage, damage to this instrument, and warranty invalidation.

- Read all instructions prior to installing, operating, and servicing the product.
- If this Reference Manual is not the correct one, call 1-800-999-9307 to request the correct Reference Manual. Save this Reference Manual for future reference.
- If you do not understand any of the instructions, contact your Emerson representative for clarification.
- Follow all warnings, cautions, and instructions marked on and supplied with the product.
- Inform and educate your personnel in the proper installation, operation, and maintenance of the product.
- Install equipment as specified in the installation instructions of the appropriate Reference Manual and per applicable local and national codes. Connect all products to the proper electrical and pressure sources.
- To ensure proper performance, use qualified personnel to install, operate, update, program, and maintain the product.
- When replacement parts are required, ensure that qualified people use replacement parts specified by Emerson. Unauthorized parts and procedures can affect the product's performance, place the safe operation of your process at risk, and VOID YOUR WARRANTY. Look-alike substitutions may result in fire, electrical hazards, or improper operation.
- Ensure that all equipment doors are closed and protective covers are in place, except when maintenance is being performed by qualified people, to prevent electrical shock and personal injury.

⚠️ WARNING

Hazardous area installation

Installations near flammable liquids or in hazardous area locations must be carefully evaluated by qualified on site safety personnel.

To secure and maintain intrinsically safe installation, use an appropriate transmitter/safety barrier/sensor combination. The installation system must be in accordance with the governing approval agency (FM, CSA, or BASEEFA/CENELEC) hazardous are classification requirements. Consult your transmitter Reference Manual for details.

Proper installation, operation, and servicing of this sensor in a hazardous area installation are entirely the operator’s responsibility.

⚠️ CAUTION

Sensor/process application compatibility

The wetted sensor materials may not be compatible with process composition and operating conditions.

Application compatibility is entirely the operator’s responsibility.

⚠️ CAUTION

Software modifications

If a 275, 375, or 475 Universal HART® Communicator is used with these transmitters, the software within the 275, 375, or 475 may require modification.

If a software modification is required, please contact your local Rosemount Service group or National Response Center at 1-800-654-7768.

1 Description and Specifications

1.1 Features and applications

Rosemount 389VP triple-junction sensors are offered with SMART capabilities. SMART options are enabled when used with Rosemount 1056, 1057, 1066, and 56 transmitters. The pH-loop capabilities include auto-recognition of the SMART sensor, automatic upload of calibration data and associated time stamp, and historical recording of pH diagnostics (slope, offset, reference impedance, and glass impedance). This trending data allows technicians to predict frequency of maintenance and estimate sensor life for a particular process condition. Additional SMART features include factory calibration, resetting SMART sensor calibration data with user menus without power cycling, and manufacturing information.

The reference junction aids in the sensor’s resistance to poisoning ions and helps prolong sensor life. Rosemount 389/389VP sensors have a triple junction reference, which protects the reference element from poisoning ions - such as ammonia, chlorine, cyanides, and sulfides - in the process. Both models are made with an outer ceramic junction constructed in an annular design around the pH/ORP sensitive membrane.

The AccuGLASS™ pH glass formulations exceed industry standards. The AccuGlass pH glass is a result of many years of glass research resulting in a formulation which has been found to increase the life of the sensor. Unlike other pH glasses presently on the market, this glass resists cracking, especially at higher temperatures, and reduces sodium ion errors commonly found in high pH applications. Overall, the AccuGlass formulation enhances the sensor performance to measure pH more accurately and have a longer sensor life than ever before.

A choice of pH glass electrodes is available to best meet various application needs. Two types are available: general purpose and high pH glass. The AccuGlass hemi bulb is the standard glass offered on both types and can be used for most applications.

The Rosemount 389VP is configured with a Variopol (VP8) sensor-to-cable connector which eliminates re-wiring and cable twisting when replacing sensors. The Variopol VP8 multiple pin connector option uses a mating VP cable. Once the cable is installed and wired to the transmitter, sensors are easily replaced without replacing the cable and without rewiring the transmitter. Also, the cable can be disconnected from the sensor before removal from the process which eliminates cable twisting. VP8 cable assemblies work with both VP8 and VP6 sensor connectors.

The Rosemount 389/389VP has a molded Tefzel body with Viton O-rings, making each sensor very robust and chemically resistant. Complete encapsulation eliminates leakage or high humidity problems traditionally found in other pH/ORP designs. The simplified construction, designed with user convenience in mind, does not require electrolyte (KCl) replenishment or any high maintenance troubleshooting procedures.

Rosemount 389/389VP sensors are combination sensors (pH, reference, and temperature within sensor body) and measure pH or ORP (oxidation/reduction potential) of aqueous solutions in pipelines, open tanks, or ponds. Rosemount 389/389VP sensors are suitable for virtually all applications and are compatible with Rosemount and other manufacturers’ instruments.
Installation is easily achieved through the wide variety of mounting configurations. These sensors feature a 1 inch (MNPT) front and rear facing connections for insertion, submersion, or flow-through pH and ORP applications.

1.4 Ordering information

The Rosemount 389 and 389VP General Purpose pH/ORP Sensors are housed in a molded Tefzel body with 1 in. MNPT forward and rear facing threads suitable for insertion, submersion, or flow through installation. The sensors can be configured with a general purpose pH, high pH, or platinum ORP electrode. Rosemount 389VP sensors are offered with SMART preamplifiers for pH measurements and standard integral preamplifiers for ORP measurements. These sensors may be configured without a preamplifier, but must be used with a remote preamplifier (i-box or transmitter). Automatic temperature compensation is standard. Sensors are available with either an integral cable connection (389) or Variopol (VP6) connector (389VP). Variopol cables sold separately (see Table 5-2).

2 Install

2.1 Unpacking and inspection

Procedure

1. Inspect the outside of the carton for any damage.
2. If damage is detected, contact the carrier immediately.
3. Inspect the hardware.
4. Make sure all the items in the packing list are present and in good condition.
5. Notify the factory if any part is missing.

2.2 Mounting

The sensor has been designed to be located in industrial process environments. Temperature and pressure limitations must not be exceeded at any time. A label regarding this matter is attached to the sensor with the cable and should not be removed.

B. 1-in. wrench opening
C. 1-in. MNPT x 2
D. T.C.
E. pH/ORP electrode

⚠️ WARNING

IRRITANT
Internal electrolyte fill may cause skin or eye irritation.

Mounting guidelines

1. Shake down the sensor to remove any air bubbles that may be present inside the tip of the pH glass.
2. Do not install the sensor horizontally. The sensor must be 10° off the horizontal to ensure accuracy.
3. Do not install the sensor upside down.
4. With the standard recessed electrode, air bubbles may become trapped in the sensor end. This problem is most commonly encountered in areas of low flow or during calibration. Shake the probe while it is immersed in solution to remove bubbles.
In most cases, the sensor can simply be installed as shipped, and you can obtain readings with an accuracy of ±0.2 pH. To obtain greater accuracy or to verify proper operation, the sensor must be calibrated as a loop with its compatible analyzer or transmitter.

2.2.1 Submersion mounting

Rosemount 389 and 389VP Sensors have a 1-in. MNPT process connection at the back of the sensor.

Procedure

1. To prevent rain water or condensation from running into the sensor, use a weatherproof junction box (see Figure 2-3).
2. Using a standard 1-in. union, mount the sensor to a 1-in. SCH 80 CPVC or PVDF standpipe.
3. Tapered pipe threads in plastic tend to loosen after installation. We therefore recommend that you use PTFE tape on the threads and check the tightness of the connection frequently to ensure that no loosening has occurred.
4. Run the sensor cable through a protective conduit for isolation from electrical interference or physical abuse from the process.
5. Install the sensor within 80° of vertical, with the electrode facing down.
   Do not run the sensor's cable with power or control wiring.

### 2.2.2 Flow through and insertion mounting

Rosemount 389 and 389VP sensors also have a 1-in. MNPT process at the front of the sensor for mounting into a 1 ⅛-in. tee or the process. See Figure 2-4 for installation configurations.
**Figure 2-4: Flow Through and Insertion Installations**

D. 1½-in. x 1-in. reducing bushing  
E. 1½-in. pipe tee  
F. 1½-in. pipe "Y"  
G. flow

**Note**
Valves and fittings by others. Mount the sensor at least 10° from horizontal.

**Note**
Do not use large pipe wrenches to tighten the sensor into a flange or other type of mounting.

## 2.3 Electrical installation

Figure 2-5 through Figure 2-19 provide the guidelines for wiring Rosemount 389/389VP sensors to various Rosemount transmitters.

1. If the cable needs to be extended, use a high quality four-conductor shielded instrument cable available from Rosemount.

**Note**
If the cable is too long, loop up the excess cable. If the cable has to be shortened, splice and terminate each conductor and make sure that the overall (outermost) drain wire is not shorted out with either of the two inner drain wires (shields).

2. Signal cable should be run in a dedicated conduit (preferably an earth grounded metallic conduit) and should be kept away from AC power lines. A spade lug kit is provided in a plastic bag wrapped around the cable.

3 Calibration

3.1 Sensor preparation

Procedure
1. Shake down the sensor to remove any air bubbles that may be present at the tip of the pH glass bulb.
2. In most cases, the pH sensor can simply be installed as shipped, and readings may be obtained with an accuracy of ±0.2 pH. To obtain greater accuracy or to verify proper operation, calibrate the sensor as a loop with its compatible transmitter.

3.2 pH calibration

1. After a temporary connection is established between the sensor and the instrument, a buffer calibration may be performed.
2. Consult the appropriate pH/ORP transmitter instruction manual for specific calibration and standardization procedures, or see below for the recommended two-point buffer calibration procedure.

3.2.1 Recommended two point buffer calibration procedure

Prerequisites
Select two stable buffer solutions, preferably pH 4.0 and 7.0. (pH buffers other than pH 4.0 and pH 7.0 can be used as long as the pH values are at least two pH units apart).

Note
A pH 7 buffer solution reads an mV value of approximately zero, and pH buffers read approximately ±59.1 mV for each pH unit above or below pH 7. Check the pH buffer manufacturer specifications for millivolt values at various temperatures, as it may affect the actual value of the buffer solution mV/pH value.

Procedure
1. Immerse the sensor in the first buffer solution. Allow the sensor to adjust to the buffer temperature (to avoid errors due to temperature differences between the buffer solution and sensor temperature) and wait for readings to stabilize. The value of the buffer can now be acknowledged by the transmitter.
2. Once the first buffer has been acknowledged by the transmitter, rinse the buffer solution off the sensor with distilled or deionized water.
3. Repeat steps 1 and 2 using the second buffer solution. Once the transmitter has acknowledged both buffer solutions, a sensor slope (mV/pH) is established (the slope value can be found within the transmitter). The slope value should read about 59.1 mV/pH for a new sensor and will decrease over
time to approximately 47 -49 mV/pH. Once the slope reads below the 47-49 mV/pH range, install a new sensor to maintain accurate readings.

### 3.2.2 Recommended pH sensor standardization

For maximum accuracy, the sensor can be standardized in-line or with a process grab sample after a buffer calibration has been performed and the sensor has been conditioned to the process. Standardization accounts for the sensor junction potential and other interferences. Standardization does not change the sensor’s slope, but simply adjusts transmitter’s reading to match that of a known process pH.

**Procedure**

1. While obtaining a process solution sample (we recommend that you take the sample close to the sensor), record the pH value that is shown on the transmitter display.
2. Measure and record the pH of the process solution sample with another temperature compensated, calibrated pH instrument. For best results, perform standardization at the process temperature.
3. Adjust the transmitter to the standardized value.

### 3.3 Rosemount™ 389/389VP ORP calibration

Most industrial applications have a number of ORP reactions occurring in sequence or simultaneously. There can be several components that are oxidized or reduced by the reagents that are used. Theoretically, the ORP potential is absolute, because it is the result of the oxidation/reduction equilibrium. However, the actual measured potential is dependent on many factors, including the condition of the surface of the ORP platinum electrode. Therefore, the sensor should be allowed 1-2 hours to become conditioned to the stream when first set up or after being cleaned.

⚠️ **WARNING**

**CORROSIVE SUBSTANCE**

The solution used during the following check is an acid and should be handled with care. Follow the directions of the acid manufacturer. Wear the proper protective equipment. Do not let the solution come in contact with skin or clothing. If contact with skin is made, immediately rinse with clean water.

**Procedure**

1. Make a temporary electrical connection between the sensor and the instrument.
2. Obtain a standard solution of saturated quinhydrone (PN R508-16OZ). To make this solution, add a few crystals of quinhydrone to either pH 4 or pH 7 buffer. Quinhydrone is only slightly soluble, but only a few crystals are required.
3. Immerse the sensor in the standard solution. Allow one to two minutes for the ORP sensor to stabilize.
4. Adjust the standardized control of the transmitter to the solution value shown in Table 3-1.
The resulting potentials, measured with a clean platinum electrode and saturated KCl/AgCL reference electrode, should be within ±20 millivolts of the value shown in Table 3-1. Note solution temperature to ensure accurate interpretation of results. The ORP value of saturated quinhydrone solution is not stable over long periods of time. Therefore, make these standards fresh each time they are used.

### Table 3-1: ORP of Saturated Quinhydrone Solution (Millivolts)

5. Remove the sensor from the buffer, rinse, and install in the process.
4 Maintenance

Rosemount™ 389/389VP sensors require minimum maintenance. Keep the sensors clean and free of debris and sediment at all times. The frequency of cleaning by wiping or brushing with a soft cloth or brush is determined by the nature of the solution being measured. Remove sensors from the process periodically and check them in buffer solutions.

⚠️ WARNING

PRESSURE AND TEMPERATURE
Before removing the sensor, be absolutely certain that the process pressure is reduced to 0 psig and the process temperature is lowered to a safe level!

If the sensor will not calibrate, refer to your transmitter reference manual for proper test procedures. If you determine that the sensor has failed, discard and replace it.

4.1 Clean electrode

If the electrode is coated or dirty, clean as follows:

Procedure

1. Remove the sensor from process.
2. Remove the sensor from process as instructed in Retractable version
3. Wipe the glass bulb with a soft, clean, lint free cloth or tissue. If this does not remove the dirt or coating, go to Step 4 (detergents clean oil and grease; acids remove scale.)
4. Wash the glass bulb in a strong detergent solution and rinse it in clean water. If this does not clean the glass bulb, go to Step 5.

⚠️ WARNING

CORROSIVE SUBSTANCE
The solution used during the following step is an acid; handle with care. Follow the directions of the acid manufacturer. Wear the proper protective equipment. Do not let the solution come in contact with skin or clothing. If contact with skin is made, immediately rinse with clean water.

5. Wash the bulb in a dilute 5% hydrochloric acid solution and rinse with clean water. Soaking the sensor overnight in the acid solution can improve cleaning action. Replace the sensor if it cannot be cleaned.
6. Following the Warning above, wash the glass bulb in dilute 5% hydrochloric acid solution and then rinse it thoroughly with clean tap water. Replace the sensor if it cannot be clean. If the glass bulb appears clean, proceed to Step 7.
7. Buffer calibrate the sensor.
Refer to Startup and calibration. If the sensor appears to respond sluggishly to pH change, soaking it overnight in a weak acid solution (5% hydrochloric acid) may improve its response. Be sure to follow the Warning above and to rinse the sensor’s tip thoroughly with tap water. If the sensor will not calibrate, it must be replaced.

4.2 Automatic temperature compensator

The temperature compensator element is a temperature sensitive resistor and can be checked with an ohmeter. Resistance increases with temperature.

The 3K element reads 3000 ohms ±1% at 77 °F (25 °C), and a Pt100 reads 110 ohms. Resistance varies with temperature for a 3K and Pt-100 element and can be determined according to Table 4-2 or the following formula:

\[ R_T = R_0 \left[1 + R_1 (T-20)\right] \]

Where \( R_T \) = Resistance and \( T \) = Temperature in °C

Refer to Table 4-1 for \( R_0 \) and \( R_1 \) values.

Table 4-1: \( R_0 \) and \( R_1 \) Values for Temperature Compensation Elements

4.3 ORP

4.3.1 Check platinum electrode

Check the platinum electrode as follows. There are two types of standard solutions which may be used to check the ORP electrode/transmitter system.

Type 1: One type of commonly used ORP standard solution is the saturated quinhydrone solution (PN R508-16OZ). Refer to Rosemount™ 389/389VP ORP calibration.

**WARNING**

The solution used during the following check is an acid.

- Handle the solution with care.
- Follow the manufacturer's directions.
- Wear the proper protective equipment.
- If contact with skin or clothing is made, immediately rinse with plenty of clean water.

Type 2: A second ORP standard solution can be prepared from the following recipe:

**Procedure**

1. Dissolve 39.2 grams of reagent grade ferrous ammonium sulfate, Fe(NH₄)₂(SO₄)₂ • 6H₂O and 48.2 grams of reagent grade ferric ammonium sulfate, FeNH₄(SO₄)₂ • 12 H₂O in approximately 700 ml of water.
   - Distilled water is preferred, but tap water is acceptable.
2. Slowly and carefully add 56.2 ml of concentrated sulfuric acid.
3. Add sufficient water to bring the total solution volume up to 1000 ml.

This standard ORP solution, although not as simple to prepare as the quinhydrone recipe, is much more stable and will maintain its millivolt value for approximately one year when stored in glass containers. This solution (ferric/ferrous ammonium sulfate) produces a nominal ORO of 476 +20 mV at 77 °F (25 ºC) when used with a saturated KCl/AgCl reference electrode and platinum measuring electrode. Some tolerance in mV values is to be expected due to the rather large liquid reference junction potentials that can arise when measuring this strongly acidic and concentrated solution. However, if measuring electrodes are kept clean and in good operating condition, consistently repeatable calibrations can be carried out using this standard solution.

4.3.2 Cleaning platinum electrode

To restore the electrode to normal operation, clean the platinum electrode with baking soda. Polish it by rubbing it with a damp paper towel and baking soda until it appears bright and shiny.
## Troubleshooting

<table>
<thead>
<tr>
<th>Trouble</th>
<th>Probable Cause</th>
<th>Remedy</th>
</tr>

Special conditions for safe use:
1. All pH/ORP sensor models with a plastic enclosure or exposed plastic parts may provide an electrostatic ignition hazard and must only be cleaned with a damp cloth to avoid the danger of ignition due to a buildup of electrostatic charge.
2. All pH/ORP sensor models with a metallic enclosure may provide a risk of ignition by impact or friction. Care should be taken during installation to protect the sensor from this risk.
3. External connections to the sensor must be suitably terminated and provide a degree of protection of at least IP20.

All pH/ORP sensor models are intended to be in contact with the process fluid and may not exceed the 900V x m criteria. This must be taken into consideration at installation.
