Introduction

Scope of Manual

This manual provides installation, adjustment, maintenance, and parts list information for the Fisher ATI actuator (figure 1). Refer to separate instruction manuals for information regarding the control valve and accessories.

Do not install, operate, or maintain an ATI actuator with Fisher NS2 Yoke without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

ATI Piston Actuator

June 2023

Description

The Spring Return Extend (SRE) ATI Actuator with Fisher NS2 Yoke is a reverse-acting, spring-opposed piston actuator that is used for operation of PV69 DS100 control valve. The Spring Return Retract (SRR) ATI Actuator with Fisher NS2 Yoke is a direct-acting, spring-opposed piston actuator that is used for operation of PV14 DS104 control valve.

The NS2 actuator yoke construction and special yoke-to-bonnet bolting provides a high structural resonant frequency that is seismically qualified for PV69 AP1000, CAP1000, and CAP1400 nuclear applications, as well as PV14 DS104 CAP1400 nuclear applications.

Specifications

Tables 1 and 2 provide specifications for the ATI Actuator with Fisher NS2 Yoke discussed in this instruction manual. All torque values given are ±5% unless otherwise specified. See the actuator nameplate for specific information for your actuator.

Educational Services

Emerson Educational Services

E-mail: education@emerson.com
emerson.com/mytraining

Maximum Pressure Limitations

The piston of the ATI actuator is pressure operated. This air pressure provides energy to compress the spring, to stroke the actuator, and move the piston away from or towards the valve. The following explanations describe the maximum pressure limits for an actuator. Refer to table 1 for maximum values.

WARNING

To avoid personal injury or parts damage, do not exceed the Maximum Pressures listed in table 1.

Exceeding any of the maximum pressures can result in uncontrolled movement of parts, damage to actuator parts and the control valve, and loss of control of the process. Use pressure-limiting or pressure-relieving devices to prevent casing pressure from exceeding these limits.

- **Maximum Casing Pressure for Actuator Sizing:** This is considered the standard full operating pressure. A full stroke of 4.0 inches of the valve is expected at this pressure. If a full stroke is not achieved, consult the troubleshooting section of this manual.
- **Maximum Casing Pressure:** If the Maximum Casing Pressure is exceeded, damage to the actuator might result.

Principle of Operation

The ATI actuator positions the valve plug in response to varying pneumatic loading pressure on the actuator. For the SRE actuator, the actuator stem moves up as the loading pressure is increased on the bottom of the piston. As the loading pressure is decreased, the spring forces the actuator stem down. For the SRR actuator, the actuator stem moves down as the loading pressure is increased on the top of the piston. As the loading pressure is decreased, the spring forces the actuator stem up.

The piston actuator has been selected to meet the requirement of the application and, in service, the actuator will produce full travel of the valve with the piston pressure as indicated on the nameplate.

Lifting Guidelines

WARNING

Failure to follow these lifting guidelines and accepted lifting and rigging practices could result in property damage and personal injury or death.

All lifting and rigging must be completed in accordance with federal/national/provincial, state and local regulations and applicable lifting and rigging equipment standards. Only personnel trained in proper lifting and rigging practices shall perform valve/actuator assembly lifting, rigging and installation. Because each lift will be unique, the method of lifting the valve assembly, the correct location for attaching and lifting the valve assembly, and what the valve assembly will do when lifted shall be considered for each lift.

Lifting and rigging equipment used to lift, install or remove a valve assembly or component must be properly selected and sized for the weight and configuration of the valve assembly or component being lifted. The weight of the complete valve assembly, including attached accessories, must be taken in consideration for this purpose. The lifting and rigging equipment must be properly maintained and inspected for damage before each use.

If the valve is supplied with an actuator or handwheel, do not use the actuator or handwheel to lift the complete valve assembly. Lifting lugs attached to the actuator must not be used to lift the complete valve assembly unless clearly marked as being rated to support the complete valve assembly weight.

Lifting lugs or other lifting equipment attached to the valve or actuator must never be used to lift or support the weight of attached piping.

NOTICE

Care must be taken when lifting the valve/actuator assembly to ensure all accessories and tubing are not damaged in the process. Accessories and tubing may need to be removed prior to lifting to prevent damage and properly reinstalled before use. Protect valve flange faces, butt weld ends, and other connection surfaces from damage during lifting.

Lifting Valve/Actuator Assembly

To lift the valve assembly, ATI actuator and accessories, the assembly should not be lifted by the actuator alone. It is also necessary to place lifting slings around the inlet and outlet of the valve body for lifting. Use padding as needed to protect any painted surfaces. The valve/actuator assembly can be lifted using a hoist capable of leveling the lifting points.

Lifting Valve Only

For guidance on lifting only the valve, please refer to the instruction manual for the applicable valve.

Lifting Actuator Only

The ATI L264.5SRE80 actuator with accessories may be lifted using the lifting ears located on the upper cartridge. The load rating for these lifting ears is 28.7 kN (6,400 lbf) and should not be exceeded. A single hoist lift point on the strap or chain will balance and lift the actuator, keeping it level. Use padding as needed to protect any painted surfaces.

The ATI L224.5SRR80 actuator with accessories may be lifted using appropriately rated hoist rings threaded into the two 3/4-10 UNC threaded holes provided in the upper head, see figure 2. The load rating for these threaded holes is 10,000 lbf (44.8 kN) combined and should not be exceeded. A single hoist lift point on the strap or chain will balance and lift the actuator, keeping it level. Use padding as needed to protect any painted surfaces.

Figure 2. Direct-Acting Piston Actuator (SSR) Top View

Installation

The actuator is normally shipped mounted on the valve body. Follow the applicable EWNS or HPNS valve instruction manual when installing the control valve in the pipeline. For information on mounting valve accessories, refer to the appropriate valve accessories instruction manual.

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

⚠ WARNING

If the control valve and actuator are installed with the actuator in any position other than vertical, the actuator may not conform with safety-related qualifications. Certain nonvertical orientations can cause water to collect in the yoke and actuator spring areas, eventually causing degradation in product performance.

Note

The ATI actuator with Fisher NS2 yoke is intended to mount directly to the valve bonnet.

Mounting the Actuator on the Valve

NOTICE

The ATI SRE actuator spring load pushes the stem down out of the actuator yoke, and it can contact the valve stem during actuator mounting. It is possible to damage valve stem threads or bend the valve stem.

It may be necessary to apply a temporary loading pressure to the actuator to move the actuator stem away from the valve during installation. See the Disassembly section of this manual.

⚠ WARNING

When moving the actuator stem with loading pressure applied, exercise caution to keep hands and tools out of the actuator stem travel path. If the loading pressure is accidentally disconnected, personal injury and property damage may result if something is caught between the actuator stem and other control valve parts.

Adjustments

Bench Set

The ATI Assembly has a pre-loaded spring; therefore, there is no bench set adjustment.

Installing the Travel Limit Switch Bracket

Refer to figure 3 when installing the limit switch targets.

1. Apply Loctite® 242 (key 185) to hex cap screws (key 147).
2. Attach the proximity switch target mounting bracket (key 148) to the stem connector half (key 103B) using the hex cap screws (key 147) and washers (key 146).
3. Center the bracket vertically on the stem connector and tighten the hex cap screws, torque to 23 N • m (17 ft • lbf).
4. Adjust the travel scale vertically to align the closed mark on the scale with the pointer on the bracket and tighten the mounting screws.

⚠ WARNING

To avoid personal injury due to the sudden, uncontrolled movement of parts, do not loosen the cap screws (key 103C) when the stem connector has spring or loading pressure force applied to it.

Operation

In a SRE, an increasing loading pressure causes the actuator stem to move upward, compressing the spring. In the event of failure of the loading pressure to the piston of the actuator, the actuator stem moves to the extreme downward position, closing the valve.

In a SRR, an increasing loading pressure causes the actuator stem to move downward, compressing the spring. In the event of failure of the loading pressure to the piston of the actuator, the actuator stem moves to the extreme upward position, opening the valve.

The nameplate attached to the top of the piston provides information about the specific construction and operating range of the actuator.

When the control valve and actuator are installed, the actuator should be checked for correct travel, freedom from excessive friction, and correct action (air-to-open or air-to-close) to match the controlling instrument. For successful operation, the actuator stem and valve plug stem must move freely in response to the loading pressure change on the piston.

Maintenance

It is recommended that the ATI assembly be replaced every 10 years.

All maintenance operations can be performed with the valve in the line.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve, as much as possible, any actuator spring precompression.

- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Replacement of Elastomeric Parts

The ATI actuator assembly contains elastomeric parts; however, these parts cannot be repaired or replaced. Instead, the entire actuator assembly is replaced after the qualified life of 10 years.

Disassembly

ATI Piston Actuator with Fisher NS2 Size 80 Yoke

Key number references are shown in figures 3 and 4.

The ATI/Yoke Piston Actuator Assembly is manufactured as an assembly as shown in figure 3. This assembly should be replaced every 10 years.

Instructions are given below for removal of the ATI piston actuator assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin reassembly at the appropriate step.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve, and drain the process media from both sides of the valve. Shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

Note

The piston actuator spring compression is pre-set; therefore, there is not a way to act against the spring before disassembly of the stem connector assembly (key 103) without the use of controlled air.

2. Remove the limit switches and set aside.

NOTICE

It is advised to remove or protect the limit switches when working around them. Inadvertent contact can cause damage.

3. Remove the tubing or piping up from the solenoid to the piston actuator regulator. Construct a portable regulator assembly shown in figure 4 and connect it to the piston actuator input (3/4 inch NPT). This will be used during disassembly and lifting of the actuator assembly in the following steps.
4. Mark a line with a suitable marker just below the locknuts (key 115) on the valve stem. This will help in assembly of the stem-connector assembly (key 103). Loosen the locknuts (key 115) down away from the stem connector assembly (key 103).
5. Using the portable regulator assembly, reset the output pressure of the regulator to 0 psig, then open the three-way valve to the piston actuator and open the isolation ball valve to the plant air.

6. For the SRE actuator, dial up the regulator output pressure until the stem connector (key 103) just barely begins to move up. For the SRR actuator, increase the pressure until the plug is seated, then back off on the pressure until the stem connector (key 103) just barely begins to move up. At this pressure the valve plug is off the main seat and the compression is relieved from the stem connector assembly (key 103).
7. Prior to disassembly of the stem connector assembly (key 103), make a mark with a suitable marker just above the stem connector (key 103) on the piston actuator piston rod. This will aid in reassembly to ensure that proper travel and seat-load is achieved on the main seat.

⚠ WARNING

To avoid personal injury due to the sudden, uncontrolled movement of parts, do not loosen the cap screws when the stem connector (key 103) when spring force is applied without the aid of control air.

8. With controlled air to the casing, loosen the stem connector cap screws (key 103C). Remove the stem connector nut-half (key 103B) leaving the magnet target assembly (key 148) in place, if possible. Remove the stem connector bolt half (key 103A) and feedback arm. Carefully follow the positioner disassembly instructions for any feedback arm used on the stem connector. Set aside.
9. Loosen the yoke-to-bonnet bolting (keys 101 and 102). Remove nuts (key 102) and washers (key 143).

⚠ WARNING

Release of air from the actuator will cause movement of the actuator stem, to avoid personal injury and property damage, keep hands and tools out of the actuator stem travel path.

10. Lift actuator off the valve by following the recommendations in the Lifting Guidelines section. Shutoff control air and vent air from piston actuator. Reset portable regulator, secure and disconnect air hose.

Assembly

ATI Piston Actuator with Fisher NS2 Size 80 Yoke

The ATI/Yoke Piston Actuator Assembly is manufactured as an assembly as shown in figure 3. This assembly should be replaced every 10 years.

Instructions are given below for remounting of the ATI piston actuator assembly. Begin assembly at the appropriate step.

1. Ensure that the locknuts (key 115) are screwed down on the valve stem. If a mark was made from disassembly, use this as a guide at step 17 of this section.
2. Coat the threads of the actuator mounting studs (key 101) with Nuclear Grade anti-seize lubricant (key 27) up to the deformed thread. Thread the actuator mounting studs (key 101) into the valve bonnet until the deformed thread prevents further insertion.
3. Connect the portable regulator assembly to the piston actuator as shown in figure 4.
4. Using the portable regulator assembly, make sure the adjusting screw of the regulator is completely backed out to ensure that the regulator outlet pressure will be 0 psig when supply pressure is introduced, then open the three-way valve to the piston actuator. Open the isolation ball valve to supply plant air to the regulator.
5. For SRE actuators, increase the regulator output pressure until the stem connector (key 103) moves all the way up into the piston actuator (fully retracted) but do not exceed the Maximum Casing Pressure listed in table 1. SRR actuators will be fully retracted without air.

6. Lower the ATI Actuator assembly onto the mounting studs (key 101), make sure that the Fisher logo on the yoke is aligned to the Fisher logo on the valve body.

Note

The following two steps require a calibrated torque wrench up to 1356 N•m (1,000 ft•lbf) for SRE actuators and up to 407 N•m (300 ft•lbf) for SRR actuators. It is helpful to number the studs (key 101)/nuts (key 102) from 1 to 12 to accurately torque the studs.

7. Coat the remaining threads of the actuator mounting studs (key 101) and the contact faces of the nuts (key 102) with Nuclear Grade anti-seize lubricant (key 27). Place the washers (key 143) over the studs (key 101) and thread the nuts (key 102) onto the studs (key 101) and hand tighten. Torque the actuator mounting nuts (key 102) in a criss-cross pattern in increments of 25% up to the full actuator mounting bolt torque value listed in table 2.
8. Check the torque of nuts by performing one (1) circular pattern to applicable actuator mounting torque in table 2.

WARNING

Release of air in the actuator will cause sudden movement of the actuator piston. Do not place hands or any body parts between the valve stem and the piston rod, as this can cause severe injury.

9. To ensure that the valve plug is fully seated, place a flat metal block at least 1 inch thick or use a flat section of the bolt half (key 103A) on its side on the top of the valve stem between the stem and the piston rod.
10. Using the portable regulator and the air venting valve in figure 4, slowly release air of the piston actuator (SRE) or increase the regulator output pressure (SRR) to extend the piston and push down on the valve stem to ensure that the valve plug is seated. Immediately stop when the valve stem ceases movement.
11. Dial the air back up (SRE) or down (SRR) until the piston is fully retracted.
12. Remove the metal block or bolt half used in steps 9 and 10.
13. Using a measuring device next to the piston, slowly extend the piston from the actuator until the piston travels to 4.00-3.95 inches (Do not exceed 4.00 inches). Hold this pressure (piston position) of the actuator for the next steps. There should be a gap between the piston rod and the valve stem.

NOTICE

Piston travel greater than 4.00 inches will result in lower seating force on the valve plug from reduced spring force.

Piston travel less than 3.95 inches may result in an excessive gap between the piston rod and valve stem, which can result in less-than-full thread engagement on the valve stem and possible thread damage.

14. Connect the nut half (key 103B) and the bolt half (key 103A) with the cap screws (key 103C) of the stem-connector to the valve stem and the connector rod, ensuring to align the nut half in the guide notch of the yoke. If there are marked lines from disassembly on the stem and piston rod, use these as guides. If there are not marks, ensure that the stem connector (key 103) threads are fully engaged on the valve stem as a minimum. Some threads can be unused and visible on the piston rod.

NOTICE

Care should be used when engaging the threads, any cross-threading should be avoided, as this may require replacing the ATI assembly or the valve stem assembly. If cross-threading has occurred, contact your [Emerson sales office](#) for guidance.

Note

To avoid cross-threading, ensure that the bolt half (key 103A) threads are engaged by pressing against the threaded piston rod as the first step in tightening, then align the nut half (key 103B) to the other side. While holding these together start the cap screws (key 103C) and tighten evenly.

Manual clamps can be used to assist in holding the stem connector halves together.

The gap between the bolt half (key 103A) and the nut half (key 103B) should be the same on both sides of the threads as the cap screws (key 103C) are tightened. If there is misalignment visible, or it appears that the threads are not engaged, restart the previous step to avoid cross-threading.

15. Tighten the cap screws (key 103C) evenly until just finger tight.
16. With the two bottom cap screws (key 103C) tight, remove the top cap screws and attach the feedback bracket to the stem connector bolt half (key 103A) with the cap screws (key 103C) and retighten. Torque the cap screws (key 103C) to 176 N•m (130 ft•lbf) in a criss-cross pattern. Carefully follow the positioner assembly instructions for any feedback arm used on the stem connector.
17. Screw the valve stem locknuts (key 115) up until the upper one contacts the bottom of the stem connector assembly (key 103). If a mark was made from disassembly, use this as a guide. Tighten until finger tight. Do not overtighten the locknuts.
18. Attach the travel scale (key 113) to the yoke using the pan head machine screws (key 126). Leave the screws finger-tight; they will be tightened after adjustment of the travel scale.
19. If not already attached, attached the target assembly per Installing the Travel Limit Switch Targets sections and align the travel scale.
20. Test the functionality of the limit switches and adjust as necessary. If significant changes to the position of the magnets appear necessary, then check the piston travel as it is likely that the travel measurement of the piston rod or thread engagement was not done properly.
21. Release pressure from the casing. Remove the portable regulator assembly.
22. Attach the air tubing provided to connect the solenoid valve to the piston actuator.

Troubleshooting

Table 3. ATI Actuator Troubleshooting

Problem	Possible Solution
Actuator Stroke is less than full rated travel	Ensure all parts are intact and assembled as specified.
	Check for debris or damaged parts that may be jamming actuator.
	Ensure stem connector is assembled as specified.
	Inspect valve, see EWNS instruction manual (D103551X012) or HPNS instruction manual (D103466X012).
Air leakage	Check for tightness of fittings.
	If leakage is from ATI seals, replace ATI assembly.
	Ensure stem connector is assembled as specified.
	Inspect valve, see EWNS instruction manual (D103551X012) or HPNS instruction manual (D103466X012).
Other	Inspect all air connections for leakage
	Contact Emerson sales office if more assistance is needed.

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always refer to this serial number when corresponding with your [Emerson sales office](#) regarding replacement parts or technical information.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Section 1: Introduction

Fisher Baumann industrial control valves (Figure 1) are intended for general utility service in pressure, flow and temperature control applications.

Industrial grade control valves exhibit low hysteresis and deadband, good control characteristics, tight shutoff, rugged construction, high performance packing and easy maintainability. This translates into reduced maintenance costs, reduced process variability and increased process availability.

1.1 Scope of the Manual

This instruction manual includes installation, maintenance and parts information for the Fisher Baumann 24000 bronze control valve.

WARNING

Do not install, operate or maintain Fisher Baumann 24000 control valves without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Section 2: Installation

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

WARNING

When ordered, the valve configuration and construction materials were selected to meet particular pressure, temperature, pressure drop and controlled fluid conditions. Responsibility for the safety of process media and compatibility of valve materials with process media rests solely with the purchaser and end-user. Because some valve body/trim material combinations are limited in their pressure drop and temperature range capabilities, do not apply any other conditions to the valve without first contacting your [Emerson sales office](#).

NOTE

The acronym of CWP may appear on the nameplate. CWP (Cold Working Pressure) denotes the pressure rating at normal ambient temperature. A normal ambient temperature range being -4 to +100°F / -20 to +38°C.

**WARNING**

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

NOTICE

To avoid damaging valve seating surfaces, make sure the adjacent piping is free of pipe scale, welding slag and any other potentially damaging material.

1. Before installing the valve in the pipeline, inspect the valve body to be certain it is free of foreign material and thoroughly clean the line of all dirt, welding chips, scale, oil or grease and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated by the arrow cast on the valve body.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. In case of a heat-insulated installation, insulate the valve body only, not the bonnet.

2.1 Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT to the lower diaphragm case.
2. Use 6.4 mm / 1/4 in. O.D. tubing or equivalent for all air lines. If air line exceeds 8 m / 25 ft in length, 9.5 mm / 3/8 in. tubing is preferred. Air pressure not to exceed 2.41 barg / 35 psig.

2.2 Disassembly

NOTICE

When assembling or disassembling the valve, do not turn the valve stem while the plug is in contact with the valve seat. This can damage the seating surface very quickly.

When adjusting the valve stem do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem and cause damage to the packing in the valve. Instead, counter-tighten the two locknuts (key 27) on the stem (key 5) together. This will allow you to turn the stem by turning the locknuts (key 27) with a wrench.

When placing the valve in a vise, clamp the flat end faces of the valve. Do not try to clamp the rounded sides of the valve. This will ruin the valve.

Actuator Removal

Access to the internal components of the valve body can be accomplished with the actuator removed. For actuator maintenance see the Fisher Baumann Pneumatic Actuator Instruction Manual (D103352X012).

Air-to-Close Actuators

1. Disconnect air supply to the actuator and remove air tubing.
2. Loosen drive nut (key 9) and then remove plug and stem (keys 4 and 5) assembly by holding actuator stem still while unthreading plug and stem assembly counterclockwise.
3. Remove stem locknuts (key 27), travel indicator (key 58) and yoke drive nut (key 9).
4. Remove actuator from valve.
5. Disconnect air supply to actuator and remove air tubing.

Air-to-Open Actuators

1. Using flexible tubing, apply sufficient air pressure to the actuator to lift the plug off the seat.
2. Loosen drive nut (key 9) and then remove plug and stem (keys 4 and 5) assembly by holding actuator stem still while unthreading plug and stem assembly counterclockwise.
3. Remove stem locknuts (key 27), travel indicator (key 58) and yoke drive nut (key 9).
4. Remove actuator from valve.
5. Disconnect air supply to actuator and remove air tubing.

Valve Body Disassembly

1. After removing the actuator, unscrew bonnet (key 8) and plug and stem (keys 4 and 5) from valve body (key 1). A new body gasket (key 49) should be installed each time the valve is disassembled.
2. Loosen packing spring load by removing the packing follower (key 10).
3. Remove the plug and stem assembly by pulling it out through the bottom of the bonnet (key 8) while rotating the stem (key 5). This will help prevent damage to the packing components.

NOTE

Handle the parts carefully to avoid damaging the seating and guiding surfaces. Wipe the parts with a clean soft cloth and examine for signs of wear or damage.

4. Use a seat ring tool made according to the dimensions in Figure 2 and Table 2 to remove the seat ring (key 2) as follows:
 - a. Insert the tool into the valve body. Be certain the tool lugs are engaged in the corresponding recesses in the seat ring.
 - b. Use a 1/2-in. drive breaker bar or impact wrench having sufficient torque capability to remove the seat ring. Seat ring installation torque is provided in Table 3 for reference. Connect the breaker bar or impact wrench and if needed, a impact-rated extension bar, to the square drive of the seat ring tool.
 - c. Remove the seat ring (key 2) from the valve body. Make sure the seat ring tool is held at a right angle to the seat ring during removal to prevent the tool from disengaging from the lugs of the seat ring.
 - d. Inspect parts for wear or damage that would prevent proper operation of the valve body.

Figure 2. Seat Ring Tool Dimensions

NOTE:
1. MAX ALLOWABLE CENTER DRILL $\varnothing$ 0.532

2.3 Lapping the Valve Seat

If valve seat leakage becomes excessive, it may be necessary to lap the valve seat.

Lapping is the process of mating the valve plug to the seat ring, with an abrasive to produce a close fit. When valve seat leakage becomes excessive, lapping becomes necessary. The plug and seat ring seating surfaces should be free of large scratches or dents and the contact surface of the seats should be as narrow as possible.

1. Use a good quality lapping compound with a mixture that contains 280 to 600 grit. Apply at several spots around the plug seating surface. Replace the plug (key 4) in the bonnet (key 8).
2. Screw the bonnet (key 8) loosely into the valve body (key 1) to serve as a guide during the lapping operation.
3. Lap the valve by applying a slight pressure on the stem and rotate the stem in short oscillating strokes approximately 8 to 10 times or until you see an even and complete lap line. The plug should be intermittently lifted and turned 90 degrees while lapping to keep the plug and seat ring concentric.
4. Clean the valve seat (key 2) and plug (key 4) thoroughly when the lapping is complete, removing all traces of lapping compound.

2.4 Replacing Packing

Refer to the standard and optional packing constructions (Figures 4 and 5) to determine the packing that has been preinstalled in your valve.

1. Disassemble the valve as directed earlier. Remove the locknuts (key 27) and indicator disk (key 58) and turn the plug stem (key 5) out through the packing box. Remove the packing box and packing. Push out the old packing by working from the underside of the bonnet (key 8).
2. For Standard Spring Loaded PTFE V-Ring Packing (Figure 4): Carefully insert each piece in exact order shown in Figure 4. Tighten the follower (key 10) until it shoulders on the bonnet (key 8). This will compress the packing spring (key 6) to enable constant stem sealing throughout packing life.
3. For Optional Molded Graphite Ribbon Packing (Figure 5): Carefully insert each piece in exact order shown in Figure 5. Hand tighten packing follower (key 10). Use a wrench to increase tightness by turning the nut an additional 60 degrees.

2.5 Actuator and Valve Body Reassembly

Before installing seat ring in valve body, thoroughly clean the threads in the valve body port. Apply suitable lubricate to the threads and tighten to torque specified in Table 3. Remove all excess lubricant after tightening.

Insert a new valve body gasket (key 49) and install bonnet assembly (key 8). Place the actuator yoke over stem (key 5). While tilting actuator back, drop yoke drive nut (key 9) over stem (key 5). Run lock nuts (key 27) and travel indicator (key 58) down as far as possible and counter tighten locknuts (key 27) to lock.

Carefully position actuator over stem (key 5), lift plug stem and turn plug stem (key 5) into actuator stem as far as it will go before adjusting bench range. See the Fisher Baumann Pneumatic Actuator Instruction Manual (D103352X012).

NOTICE

When assembling or disassembling the valve, do not turn the valve stem while the plug is in contact with the valve seat. This can damage the seating surface very quickly.

Figure 3. Fisher Baumann 24000 Valve Body Assembly with Standard Bonnet and Standard PTFE Spring Loaded Packing

E1259

WARNING

To avoid personal injury or equipment damage due to possible sudden shifting or falling of the valve assembly, do not lift the valve by the handwheel.

Section 3: Maintenance

WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out under pressure when removing the packing hardware or packing rings or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTE

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

Section 4: Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name and desired material using the following parts tables.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and could cause personal injury and property damage.

Section 1: Introduction

Fisher Baumann 24000C carbon steel industrial control valves (Figure 1) are intended for general utility service in pressure, flow and temperature control applications.

1.1 Scope of the Manual

This instruction manual includes installation, maintenance and parts information for the Fisher Baumann 24000C control valve.

WARNING

Do not install, operate or maintain Fisher Baumann 24000C control valves without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Figure 1. 24000C Control Valve with Fisher Baumann 32 Actuator

w9743-1

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

WARNING

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

NOTE

The acronym of CWP may appear on the nameplate. CWP (Cold Working Pressure) denotes the pressure rating at normal ambient temperature. A normal ambient temperature range being -4 to +100°F / -20 to +38°C.

WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

Section 2: Maintenance

WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out under pressure when removing the packing hardware or packing rings or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTE

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

WARNING

Avoid personal injury or property damage by thoroughly cleaning the line of all dirt, welding chips, scale, oil or grease and other foreign material. Failure to do so could result in damage to the seating and sealing surfaces of the valve and result in damage to the valve and release of process materials.

Section 3: Installation

Refer to key numbers in Figure 3 unless otherwise specified.

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated by the arrow cast on the valve body.
3. A three-valve bypass would permit removal of the control valve from the line without shutting down the system.
4. In case of a heat-insulated installation, insulate the valve body only, not the bonnet.

WARNING

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation. The valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

3.1 Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT opening in the lower diaphragm case.
2. Use 6.4 mm / 1/4 in. O.D. tubing or equivalent for all air lines. If air line exceeds 8 m / 25 ft in length, 9.5 mm / 3/8 in. tubing is preferred. Air pressure should not exceed 2.5 barg / 35 psig.

CAUTION

- **When assembling or disassembling the valve, do not turn the valve stem while the plug is touching the valve seat. This will damage the valve's seating surfaces.**
- **When adjusting the valve stem do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem and cause damage to the packing in the valve. Instead, counter-tighten the two locknuts (key 27) on the stem (key 5). This will allow you to turn the stem by turning the locknuts (key 27) with a wrench.**
- **When placing valve in a vise, clamp the flat end faces of the valve. Do not clamp the rounded sides of the valve. This will distort the shape of the casting and will ruin the valve.**

3.2 Disassembly

1. Mount the valve in a vise by clamping flat end faces of the valve (Figure 3). Caution must be taken not to damage the serrated flange faces.
2. Remove the actuator, stem locknuts (key 27), travel indicator (key 58) and yoke drive nut (key 9).
3. Turn the bonnet (key 8) in a counter-clockwise direction from the valve body (key 1). Remove the O-ring (key 12) and remove and discard the valve body gasket (key 49). A new gasket should be installed each time the valve is disassembled.
4. Pull the plug and stem assembly (keys 4 and 5) out through the bottom of the bonnet. Rotate the assembly to prevent damage to the packing. Wipe the parts with a clean soft cloth and examine for signs of wear.

CAUTION

Handle the parts carefully to avoid damaging the seating and guiding surfaces.

5. Use a seat ring tool made according to the dimensions in Figure 2 and Table 1 to remove the seat ring (key 2) as follows:
 - a. Insert the tool into the valve body. Be certain the tool lugs are engaged in the corresponding recesses in the seat ring.
 - b. Use a 1/2 in. drive breaker bar or impact wrench having sufficient torque capability to remove the seat ring. Seat ring installation torque is provided in Table 2 for reference. Connect the breaker bar or impact wrench and if needed, an impact-rated extension bar, to the square drive of the seat ring tool.
 - c. Remove the seat ring (key 2) from the valve body. Make sure the seat ring tool is held at a right angle to the seat ring during removal to prevent the tool from disengaging from the lugs of the seat ring.
 - d. Inspect parts for wear or damage that would prevent proper operation of the valve body.

2. Female end used for port diameters 0.8125 and 1.0625.

3.3 Lapping the Valve Seat

If valve seat leakage becomes excessive, it may be necessary to lap the valve seat.

Lapping is the process of mating the valve plug to the seat ring, with an abrasive to produce a close fit. When valve seat leakage becomes excessive, lapping becomes necessary. The plug and seat ring seating surfaces should be free of large scratches or dents and the contact surface of the seats should be as narrow as possible.

1. Use a good quality lapping compound with a mixture that contains 280 to 600 grit. Apply at several spots around the plug seating surface. Replace the plug (key 4) in the bonnet (key 8).
2. Place the bonnet (key 8) loosely into the valve body (key 1) to serve as a guide during the lapping operation.
3. Lap the valve by applying a slight pressure on the stem and rotate the stem in short oscillating strokes approximately 8 to 10 times or until you see an even and complete lap line. The plug should be intermittently lifted and turned 90 degrees while lapping to keep the plug and seat ring concentric.
4. Clean the valve seat and plug (key 4) thoroughly when the lapping is complete, removing all traces of lapping compound.

3.4 Replacing Packing

Refer to the standard packing construction and the optional packing shown in Figures 3, 4 and 5 to determine the packing that has been preinstalled in your valve.

1. Disassemble the valve as directed earlier. Remove the locknuts (key 27) and indicator disk (key 58) and turn the plug and stem (keys 4 and 5) out through the packing box. Remove the packing follower (key 10). Push out the old packing (key 14) by working from the underside of the bonnet (key 8).
2. Standard spring loaded PTFE V-ring packing (Figures 3 and 4): Insert each piece in exact order shown in Figures 3 and 4. Hand tighten the packing follower (key 10) until it shoulders on the bonnet (key 8). This will compress the packing spring (key 6), to enable constant stem sealing throughout the packing life.
3. Molded graphite (flexible graphite) packing (Figure 5): Insert each piece in exact order shown in the Figure 5. Hand tighten the packing follower (key 10). Use a wrench to increase tightness by turning the nut an additional 60 degrees.

3.5 Actuator and Valve Body Reassembly

1. Before installing seat ring in valve body, thoroughly clean the threads in the valve body port. Apply suitable lubricate to the threads and tighten to torque specified in Table 2. Remove all excess lubricant after tightening.
2. Insert a new valve body gasket (key 49) and install the bonnet assembly (key 8) with the plug and stem assembly in the valve. The O-ring (key 12) must be reinstalled by gently stretching over the bonnet and snapping into the gap between the top of the valve body (key 1) and the bonnet (key 8). This O-ring acts as a dust/moisture seat.
3. Place the actuator yoke over the stem (key 5). While tilting the actuator back, drop the yoke drive nut (key 9) over the stem (key 5). Run the locknuts (key 27) and travel indicator (key 58) down as far as possible and counter tighten the locknuts (key 27) to lock.

See the Fisher Baumann Pneumatic Actuator Instruction Manual ([D103352X012](#)) for reassembly and bench range adjustment.

CAUTION

When assembling or disassembling the valve, do not turn the valve stem while the plug is in contact with the valve seat. This can damage the seating surface very quickly.

Section 4: Parts

4.1 Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name and desired material using the following parts tables.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and could cause personal injury and property damage.

Figure 1. Baumann Control Valve with FIELDVUE™ Digital Valve Controller

Introduction

The Baumann 24000CVF and 24000SVF line of pneumatic control valves (figure 1) may be used for the control of pressure, temperature, level, and flow. These valves are available with CL150 or 300 and EN PN10-40 flanged end connections.

The high performance 24000CVF and SVF designs feature low deadband and hysteresis, high flow capacity, superb control characteristics, tight shutoff, and advanced packing systems to meet demanding service conditions. The rugged, compact and light weight control valves are ideal for use in tight piping systems where space is a premium.

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for the Baumann 24000CVF carbon steel and SVF stainless flanged control valves.

Do not install, operate, or maintain Baumann 24000CVF or 24000SVF control valves without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

⚠ WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

⚠ WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

Educational Services

For information on available courses for Baumann 24000CVF/SVF valves, as well as a variety of other products, contact:

Emerson Automation Solutions

Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Note

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

Installation

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease, and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated by the arrow cast on the valve body.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. In case of a heat-insulated installation, insulate the valve body only, not the bonnet.

⚠ WARNING

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation. The valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.
2. Use 6.4 mm (1/4 inch) O.D. tubing or equivalent for all air lines. If air line exceeds 8 m (25 ft) in length, 9.5 mm (3/8 inch) tubing is preferred. Air lines must not leak. Air pressure not to exceed 2.5 barg (35 psig).

Disassembly

⚠ WARNING

If there is evidence of process fluid under pressure leaking from the joint, retighten the valve body/joint nuts. Return to the Warning at the beginning of the Maintenance section to ensure proper steps have been taken to isolate the valve and relieve process pressure.

CAUTION

- When assembling or disassembling the valve, do not turn the valve stem while the plug is touching the valve seat. This will damage the valve's seating surfaces.
- When adjusting the valve stem, do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem, and cause damage to the packing in the valve. Instead, counter-tighten the two locknuts (key 27) on the stem (key 5). This will allow you to turn the stem by turning the locknuts (key 27) with a wrench.
- When placing the valve in a vise, do not clamp the rounded sides of the valve. This will distort the shape of the casting, and will ruin the valve. Caution must be taken not to damage the serrated flange faces.
- Mount the valve in a vise by clamping one flange below the serrated surface. Caution must be taken not to damage the serrated flange faces.

Actuator Removal

Access to the internal components of the valve body can be accomplished with the actuator removed. For actuator maintenance see the Baumann Pneumatic Actuators Instruction Manual ([D103352X012](#)).

Air-to-Close Actuators

1. Disconnect the air supply to the actuator and remove the air tubing.
2. Loosen the drive nut (key 9) and then remove the plug and stem (keys 4 and 5) assembly by holding the actuator stem still while unthreading the plug and stem assembly clockwise.
3. Remove the stem locknuts (key 27), travel indicator (key 58), and yoke drive nut (key 9).
4. Remove the actuator from the valve.

Air-to-Open Actuators

1. Using flexible tubing, apply sufficient air pressure to the actuator to lift the plug off the seat.
2. Loosen the drive nut (key 9) and then remove the plug and stem (keys 4 and 5) assembly by holding the actuator stem still while unthreading the plug and stem assembly clockwise.
3. Remove the stem locknuts (key 27), travel indicator (key 58), and yoke drive nut (key 9).
4. Remove the actuator from the valve.
5. Disconnect the air supply to the actuator and remove the air tubing.

Valve Body Disassembly

1. After removing the actuator, remove the hex nuts (key 12), lift bonnet (key 8), and plug and stem (keys 4 and 5) from the valve body (key 1). A new valve body gasket (key 49) should be installed each time the valve is disassembled.
2. Loosen the packing spring load by removing the packing follower (key 10).

Remove the plug and stem assembly by pulling it out through the bottom of the bonnet (key 8) while rotating the stem (key 5). This will help prevent damage to the packing components.

Note

Handle the parts carefully to avoid damaging the seating and guiding surfaces. Wipe the parts with a clean soft cloth and examine for signs of wear or damage.

3. Use a seat ring tool made according to the dimensions in figure 2 and table 1 to remove the seat ring (key 2) as follows:
 - a. Insert the tool into the valve body. Be certain the tool lugs are engaged in the corresponding recesses in the seat ring.
 - b. Use a 1/2 inch drive breaker bar or impact wrench having sufficient torque capability to remove the seat ring. Seat ring installation torque is provided in table 2 for reference. Connect the breaker bar or impact wrench, and if needed, a impact-rated extension bar, to the square drive of the seat ring tool.
 - c. Remove the seat ring (key 2) from the valve body. Make sure the seat ring tool is held at a right angle to the seat ring during removal to prevent the tool from disengaging from the lugs of the seat ring.
 - d. Inspect parts for wear or damage that would prevent proper operation of the valve body.

1. Male end used for trim 151, 177, and port diameters .25 and .375

2. Female end used for port diameters .8125 and 1.0625

4. Low Flow Trims:

- e. For Baumann 151 trim (figure 5) unscrew the seat subassembly (key 51) from the seat ring (key 2) with a 5/8 inch socket wrench. When reassembling, hand tighten the subassembly (key 51) and then rotate 1/8 of a turn with the 5/8 inch socket to lock in place.

Note

If changing to Baumann 151 trim, for correct flow characteristics, be sure the valve is reversed in the pipeline so that flow direction is flow down.

- f. For Baumann 177 trim (figure 6) unscrew the retainer nut (key 24) using a 3/4 inch socket wrench. Remove the gland (key 23) and insert (key 25). Replace the insert (key 25), making sure that the tapered portion faces up. If replacement of the housing (key 26) is required, use a 5/8 inch socket wrench.
5. NOLEEK Bellows Trim: Refer to figure 7 and table 9. Hold the bellows bonnet and push down on the stem to expose the plug retaining pin (key 21). Using a small punch, tap pin (key 21) out. To replace the new plug retaining pin (key 21), be sure the plug and stem are aligned to expose the hole (figure 7). With a needle nose pliers, slide the pin (key 21) into the hole.

⚠ WARNING

Be sure the plug retaining pin (key 21) is flush inside the hole and not exposed on either side of the plug or damage could happen to the bonnet interior.

Lapping the Valve Seat

If valve seat leakage becomes excessive, it may be necessary to lap the valve seat.

Lapping is the process of mating the valve plug to the seat ring, with an abrasive to produce a close fit. When valve seat leakage becomes excessive, lapping becomes necessary. The plug and seat ring seating surfaces should be free of large scratches or dents and the contact surface of the seats should be as narrow as possible.

1. Disassemble the valve body and remove the plug and stem assembly (keys 4 and 5) as directed in the previous Valve Body Disassembly section in this instruction manual.
2. Use a good quality lapping compound with a mixture that contains 280 to 600 grit. Apply at several spots around the plug seating surface. Replace the plug and stem carefully in the bonnet.
3. Install the bonnet (key 8) into the valve body, without gasket and hand tighten. The bonnet will serve as a guide during the lapping operation.
4. Lap the valve by applying a slight pressure on the stem and rotate the stem in short oscillating strokes approximately 8 to 10 times or until you see an even and complete lap line. The plug should be intermittently lifted and turned 90 degrees while lapping to keep the plug and seat ring concentric.
5. Clean the valve seat and plug (key 4) thoroughly when lapping is complete, removing all traces of lapping compound.
6. Reinsert the plug and stem assembly through the bottom of the bonnet (key 8) by slowly rotating through the packing. Be careful not to damage the packing rings.

Replacing Packing

Refer to figure 3 and the standard and optional packing constructions (figure 8) to determine the packing that has been preinstalled in your valve.

1. Disassemble the valve as directed earlier. Remove the locknuts (key 27) and travel indicator (key 58), and turn the plug stem (key 5) out through the packing box. Remove the packing follower (key 10). Push out the old packing (key 14) by working from the underside of the bonnet (key 8).
2. **Standard Spring Loaded PTFE V-Ring Packing (figures 3 and 8):** Carefully insert each piece in exact order shown in figure 8. Turn the packing follower (key 10) until it shoulders on the bonnet (key 8). This will compress the packing spring (key 6) to enable constant stem sealing throughout packing life.
3. **Molded Graphite Ribbon Packing (figure 8):** Carefully insert each piece in exact order shown in figure 8. Hand tighten the packing follower (key 10). Use a wrench to increase tightness by turning the follower an additional 60 degrees.
4. **ENVIRO-SEAL™ Packing (figure 8):** Carefully insert each piece in exact order as shown in figure 8. Tighten the packing follower (key 10) until the Belleville springs are compressed. This will be signaled by a significant increase in resistance. Back off the follower 1/8 to 1/4 turn. A gap of approximately 1.5 mm (1/16 inch) between the packing follower and the bonnet will ensure the packing is seated properly.
5. **For the optional NOLEEK bellows bonnet (not available with Baumann 24000CVF carbon steel valves):**

NOLEEK bellows seal packing (figure 7, table 9): Insert each piece in the exact order shown in the illustration. Hand tighten the packing follower (key 10).

Actuator and Valve Body Reassembly

1. Before installing seat ring in valve body, thoroughly clean the threads in the valve body port. Apply suitable anti-seize lubricant to the threads and tighten to torque specified in table 2. Remove all excess lubricant after tightening.
2. Insert a new valve body gasket (key 49) and install the bonnet assembly (key 8). For NPS 1/2 to 1 valves, tighten the nuts (key 12) to torque of 9.5-17.6 N•m (7-13 lbf•ft); NPS 1-1/2 to 2 valves, tighten nuts (key 12) to torque of 21.7-42.0 N•m (16-31 lbf•ft).

3. Place the actuator yoke over the stem (key 5). While tilting the actuator back, drop the yoke drive nut (key 9) over the stem (key 5). Run the locknuts (key 27), and the travel indicator (key 58), down as far as possible and counter tighten the locknuts (key 27) to lock.

See the Baumann Pneumatic Actuators Instruction Manual ([D103352X012](#)) for reassembly and bench range adjustment.

CAUTION

When assembling or disassembling the valve, do not turn the valve stem while the plug is in contact with the valve seat. This can damage the seating surface very quickly.

⚠ WARNING

To avoid personal injury or equipment damage due to possible sudden shifting or falling of the valve assembly, do not lift the valve assembly by the handwheel.

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name, and desired material using the following parts tables.

⚠ WARNING

Use only genuine Fisher™ replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Special ENVIRO-SEAL Packing Note

The ENVIRO-SEAL PTFE packing system is suitable for 100 ppm environmental applications on services up to 51.7 barg (750 psig) and process temperatures ranging from -46 to 232°C (-50 to 450°F).

For non-environmental applications, this packing system offers excellent performance at the same temperature range up to the maximum valve working pressure.

Temperature limits apply to packing arrangements only. Complete valve assembly temperature limits may differ. Refer to appropriate pressure/ temperature ratings.

Reference the Packing Selection Guidelines for Fisher Sliding Stem Valves Bulletin 59.1:062 ([D101986X012](#)).

Figure 1. 24000F Control Valve

Introduction

The Baumann 24000F Wafer Body Control Valve (figures 1) mates with ASME and EN line flange connections and is designed to control a wide range of process liquids, gases and vapors. This compact package provides the connection integrity of flanged body globe valves while being significantly lighter and easier to install.

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for the Baumann 24000F wafer body control valve.

Do not install, operate, or maintain Baumann 24000F control valves without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

⚠ WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

⚠ WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

⚠ WARNING

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Note

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

WARNING

Avoid personal injury or property damage by thoroughly cleaning the line of all dirt, welding chips, scale, oil or grease, and other foreign material. Failure to do so could result in damage to the seating and sealing surfaces of the valve and result in damage to the valve and release of process materials.

Installation

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease, and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated by the arrow cast on the valve body.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. In case of a heat-insulated installation, insulate the valve body only, not the bonnet.

WARNING

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation. The valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.

2. Use 6.4 mm (1/4 inch) O.D. tubing or equivalent for all air lines. If air line exceeds 8 m (25 ft) in length, 9.5 mm (3/8 inch) tubing is preferred. Air lines must not leak. Air pressure not to exceed 2.5 bar (35 psig).

Disassembly

⚠ WARNING

If there is evidence of process fluid under pressure leaking from the joint, retighten the valve body/joint nuts. Return to the Warning at the beginning of the Maintenance section to ensure proper steps have been taken to isolate the valve and relieve process pressure.

CAUTION

- When assembling or disassembling the valve, do not turn the valve stem while the plug is touching the valve seat. This will damage the valve's seating surfaces.
- When adjusting the valve stem, do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem, and cause damage to the packing in the valve. Instead, counter-tighten the two locknuts (key 27) on the stem (key 5). This will allow you to turn the stem by turning the locknuts (key 27) with a wrench.
- When placing the valve in a vise, do not clamp the rounded sides of the valve. This will distort the shape of the casting, and will ruin the valve.

Actuator Removal

Access to the internal components of the valve body can be accomplished with the actuator removed. For actuator maintenance see the following instruction manual ([D103352X012](#)).

Air-to-Close Actuators

1. Disconnect the air supply to the actuator and remove the air tubing.
2. Loosen the drive nut (key 9) and then remove the plug and stem (keys 4 and 5) assembly by holding the actuator stem still while unthreading the plug and stem assembly counterclockwise.
3. Remove the stem locknuts (key 27), travel indicator (key 58), and yoke drive nut (key 9).
4. Remove the actuator from the valve.

Air-to-Open Actuators

1. Using flexible tubing, apply sufficient air pressure to the actuator to lift the plug off the seat.
2. Loosen the drive nut (key 9) and then remove the plug and stem (keys 4 and 5) assembly by holding the actuator stem still while unthreading the plug and stem assembly counterclockwise.
3. Remove the stem locknuts (key 27), travel indicator (key 58), and yoke drive nut (key 9).
4. Remove the actuator from the valve.
5. Disconnect the air supply to the actuator and remove the air tubing.

Valve Body Disassembly

1. After removing the actuator, unscrew the bonnet (key 8), and plug and stem (keys 4 and 5) from valve body (key 1). A new body gasket (key 49) should be installed each time the valve is disassembled.

2. Loosen the packing spring load by removing the packing follower (key 10).

Remove the plug and stem assembly by pulling it out through the bottom of the bonnet (key 8) while rotating the stem (key 5). This will help prevent damage to the packing components.

Note

Handle the parts carefully to avoid damaging the seating and guiding surfaces. Wipe the parts with a clean soft cloth and examine for signs of wear or damage.

3. To remove the seat ring (key 2), use a 5/8 inch socket wrench. Clean the seat ring thoroughly and examine for signs of wear or damage.
4. Low Flow Trims:
 - a. For Baumann 151 trim (figure 5) unscrew the seat subassembly. When reassembling, hand tighten the subassembly (key 51) and then rotate 1/8 of a turn with the 5/8 inch socket to lock in place.

Note

If changing to Baumann 151 trim, for correct flow characteristics, be sure the valve is reversed in the pipeline so that flow direction is flow-to-close.

- b. For Baumann 177 trim (figure 6) unscrew the retainer nut (key 24) using a 3/4 inch socket wrench. Remove the gland (key 23) and insert (key 25). Replace the insert (key 25), making sure that the tapered portion faces up. If replacement of the housing (key 26) is required, use a 5/8 inch socket wrench.

Lapping the Valve Seat

If valve seat leakage becomes excessive, it may be necessary to lap the valve seat.

Lapping is the process of mating the valve plug to the seat ring, with an abrasive to produce a close fit. When valve seat leakage becomes excessive, lapping becomes necessary. The plug and seat ring seating surfaces should be free of large scratches or dents and the contact surface of the seats should be as narrow as possible.

1. Disassemble the valve body and remove the plug and stem assembly (keys 4 and 5) as directed in the previous Valve Body Disassembly section in this instruction manual.
2. Use a good quality lapping compound with a mixture that contains 280 to 600 grit. Apply at several spots around the plug seating surface. Replace the plug and stem carefully in the bonnet.
3. Install the bonnet (key 8) into the valve body, without gasket and hand tighten. The bonnet will serve as a guide during the lapping operation.
4. Lap the valve by applying a slight pressure on the stem and rotate the stem in short oscillating strokes approximately 8 to 10 times or until you see an even and complete lap line. The plug should be intermittently lifted and turned 90 degrees while lapping to keep the plug and seat ring concentric.
5. Clean the valve seat and plug (key 4) thoroughly when lapping is complete, removing all traces of lapping compound.
6. For the NPS 1 integral seat body, inspect internal seating surface for wear or damage and replace if necessary.

Replacing Packing

Refer to figure 2 and the standard and optional packing constructions (figures 7, 8, and 9) to determine the packing that has been preinstalled in your valve.

1. Disassemble the valve as directed earlier. Remove the locknuts (key 27) and indicator disk (key 58), and turn the plug stem (key 5) out through the packing box. Remove the packing follower (key 10). Push out the old packing (key 14) by working from the underside of the bonnet (key 8).
2. **Standard Spring Loaded PTFE V-Ring Packing (figures 2 and 7):** Carefully insert each piece in exact order shown in figure 7. Turn the packing follower (key 10) until it shoulders on the bonnet (key 8). This will compress the packing spring (key 6) to enable constant stem sealing throughout packing life.
3. **Molded Graphite Ribbon Packing (figure 8):** Carefully insert each piece in exact order shown in figure 8. Hand tighten the packing follower (key 10). Use a wrench to increase tightness by turning the follower an additional 60 degrees.
4. **ENVIRO-SEAL™ Packing (figure 9):** Carefully insert each piece in exact order as shown in figure 9. Tighten the packing follower (key 10) until the Belleville springs are compressed. This will be signaled by a significant increase in resistance. Back off the follower 1/8 to 1/4 turn. A gap of approximately 1.5 mm (1/16 inch) between the packing follower and the bonnet will ensure the packing is seated properly.

Actuator and Valve Body Reassembly

1. Insert a new valve body gasket (key 49) and install the bonnet assembly (key 8).
2. Place the actuator yoke over the stem (key 5). While tilting the actuator back, drop the yoke drive nut (key 9) over the stem (key 5). Run the locknuts (key 27), and the travel indicator (key 58), down as far as possible and counter tighten the locknuts (key 27) to lock.
3. Carefully position the actuator over the stem (key 5), lift the plug stem (key 5) and turn the plug stem (key 5) into the actuator stem as far as it will go before adjusting the bench range.

See the following instruction manual (Baumann Actuator Instructions, [D103352X012](#)) for reassembly and bench range adjustment.

CAUTION

When assembling or disassembling the valve, do not turn the valve stem while the plug is in contact with the valve seat. This can damage the seating surface very quickly.

⚠ WARNING

To avoid personal injury or equipment damage due to possible sudden shifting or falling of the valve assembly, do not lift the valve assembly by the handwheel.

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name, and desired material using the following parts tables.

⚠ WARNING

Use only genuine Fisher™ replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Special ENVIRO-SEAL Packing Note

The ENVIRO-SEAL PTFE packing system is suitable for 100 ppm environmental applications on services up to 51.7 barg (750 psig) and process temperatures ranging from -46 to 232°C (-50 to 450°F).

For non-environmental applications, this packing system offers excellent performance at the same temperature range up to the maximum valve working pressure.

Temperature limits apply to packing arrangements only. Complete valve assembly temperature limits may differ. Refer to appropriate pressure/ temperature ratings.

Section 1: Introduction

The Fisher Baumann 24000S line of stainless steel pneumatic control valves (Figure 1) may be used for the control of pressure, temperature, level and flow. NPS 1/2 through 2 valves are available with NPT end connections. NPS 3 is available as wafer style only. The 316 stainless steel valve body will withstand mildly corrosive fluids, yet is economical enough to use in applications where carbon steel is normally specified.

1.1 Scope of the Manual

This instruction manual includes installation, maintenance and parts information for the Fisher Baumann 24000S stainless steel control valve.

WARNING

Do not install, operate or maintain Fisher Baumann 24000S control valves without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Section 2: Installation

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

WARNING

When ordered, the valve configuration and construction materials were selected to meet particular pressure, temperature, pressure drop and controlled fluid conditions. Responsibility for the safety of process media and compatibility of valve materials with process media rests solely with the purchaser and end user. Because some valve body/trim material combinations are limited in their pressure drop and temperature range capabilities, do not apply any other conditions to the valve without first contacting your [Emerson sales office](#).

NOTE

The acronym of CWP may appear on the nameplate. CWP (Cold Working Pressure) denotes the pressure rating at normal ambient temperature. A normal ambient temperature range being -4 to +100°F / -20 to +38°C.

WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

⚠ WARNING

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

NOTICE

To avoid damaging valve seating surfaces, make sure the adjacent piping is free of pipe scale, welding slag and any other potentially damaging material.

1. Before installing the valve in the pipeline, inspect the valve body to be certain it is free of foreign material and thoroughly clean the line of all dirt, welding chips, scale, oil or grease and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated by the arrow cast on the valve body.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. In case of a heat-insulated installation, insulate the valve body only, not the bonnet.

2.1 Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.
2. Use 6.4 mm / 1/4 in. O.D. tubing or equivalent for all air lines. If air line exceeds 8 m / 25 ft in length, 9.5 mm / 3/8 in. tubing is preferred. Air lines must not leak. Air pressure not to exceed 2.5 bar / 35 psig.

Section 3: Maintenance

WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out under pressure when removing the packing hardware or packing rings or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTE

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

3.1 Disassembly

NOTICE

- When assembling or disassembling the valve, do not turn the valve stem while the plug is touching the valve seat. This will damage the valve's seating surfaces.
- When adjusting the valve stem, do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem and cause damage to the packing in the valve. Instead, counter-tighten the two locknuts (key 27) on the stem (key 5). This will allow you to turn the stem by turning the locknuts (key 27) with a wrench.
- When placing the valve in a vise, do not clamp the rounded sides of the valve. This will distort the shape of the casting, and will ruin the valve.

Actuator Removal

Access to the internal components of the valve body can be accomplished with the actuator removed. For actuator maintenance, see the Fisher Baumann Actuator Instruction Manual (D103352X012).

Air-to-Close Actuators

1. Disconnect the air supply to the actuator and remove the air tubing.
2. Loosen the drive nut (key 9) and then remove the plug and stem (keys 4 and 5) assembly by holding the actuator stem still while unthreading the plug and stem assembly counterclockwise.
3. Remove the stem locknuts (key 27), travel indicator (key 58) and yoke drive nut (key 9).
4. Remove the actuator from the valve.

Air-to-Open Actuators

1. Using flexible tubing, apply sufficient air pressure to the actuator to lift the plug off the seat.
2. Loosen the drive nut (key 9) and then remove the plug and stem (keys 4 and 5) assembly by holding the actuator stem still while unthreading the plug and stem assembly counterclockwise.
3. Remove the stem locknuts (key 27), travel indicator (key 58) and yoke drive nut (key 9).
4. Remove the actuator from the valve.
5. Disconnect the air supply to the actuator and remove the air tubing.

Valve Body Disassembly

1. After removing the actuator, unscrew the bonnet (key 8) and plug and stem (keys 4 and 5) from valve body (key 1). A new body gasket (key 49) should be installed each time the valve is disassembled.
2. Loosen the packing spring load by removing the packing follower (key 10).

Remove the plug and stem assembly by pulling it out through the bottom of the bonnet (key 8) while rotating the stem (key 5). This will help prevent damage to the packing components.

NOTE

Handle the parts carefully to avoid damaging the seating and guiding surfaces. Wipe the parts with a clean soft cloth and examine for signs of wear or damage.

3. To remove the seat ring (key 2), use a 5/8 in. socket wrench. Clean the seat ring thoroughly and examine for signs of wear or damage.
4. Low Flow Trims:
 - a. For Fisher Baumann 151 trim (Figure 6), unscrew the seat sub-assembly (key 51) with a 5/8 in. socket wrench. When reassembling, hand tighten the sub-assembly (key 51) and then rotate 1/8 of a turn with the 5/8 in. socket to lock in place.

NOTE

If changing to Fisher Baumann 151 trim, for correct flow characteristics, be sure the valve is reversed in the pipeline so that flow direction is flow-to-close.

- b. For Fisher Baumann 177 trim (Figure 7), unscrew the retainer nut (key 24) using a 3/4 in. socket wrench. Remove the gland (key 23) and insert (key 25). Replace the insert (key 25), making sure that the tapered portion faces up. If replacement of the housing (key 26) is required, use a 5/8 inch socket wrench.
- c. For NOLEEK bellows trim (Figure 8), hold the bellows bonnet and push down on the stem to expose the plug retaining pin (key 21). Using a small punch, tap the pin (key 21) out. To replace the new plug retaining pin (key 21), be sure the plug and stem is aligned to expose the hole (refer to Figure 6) and with needle nose pliers slide the pin (key 21) into the hole.

NOTICE

Be sure the plug retaining pin (key 21) is flush inside the hole and not exposed on either side of the plug or damage could happen to the bonnet interior.

3.2 Lapping the Valve Seat

If valve seat leakage becomes excessive, it may be necessary to lap the valve seat.

Lapping is the process of mating the valve plug to the seat ring, with an abrasive to produce a close fit. When valve seat leakage becomes excessive, lapping becomes necessary. The plug and seat ring seating surfaces should be free of large scratches or dents and the contact surface of the seats should be as narrow as possible.

1. Use a good quality lapping compound with a mixture that contains 280 to 600 grit. Apply at several spots around the plug seating surface. Replace the plug and stem carefully in the bonnet.
2. Install the bonnet (key 8) into the valve body, without gasket and hand tighten. The bonnet will serve as a guide during the lapping operation.
3. Lap the valve by applying a slight pressure on the stem and rotate the stem in short oscillating strokes approximately 8 to 10 times or until you see an even and complete lap line. The plug should be intermittently lifted and turned 90 degrees while lapping to keep the plug and seat ring concentric.
4. Clean the valve seat and plug (key 4) thoroughly when lapping is complete, removing all traces of lapping compound.
5. For the NPS 1 through 3 integral seat valve body, inspect the internal seating surface for wear or damage and replace if necessary.

3.3 Replacing Packing

Refer to Figure 4 and the standard and optional packing constructions (Figure 9) to determine the packing that has been preinstalled in your valve.

1. Disassemble the valve as directed earlier. Remove the locknuts (key 27) and indicator disk (key 58) and turn the plug and stem (keys 4 and 5) out through the packing box. Remove the packing follower (key 10). Push out the old packing (key 14) by working from the underside of the bonnet (key 8).
2. Standard Spring Loaded PTFE V-Ring Packing (Figures 4 and 9): Carefully insert each piece in exact order shown in Figure 9. Tighten the packing follower (key 10) until it shoulders on the bonnet (key 8). This will compress the packing spring (key 7) to enable constant stem sealing throughout packing life.
3. Molded Graphite Ribbon Packing (Figure 9): Carefully insert each piece in exact order shown in Figure 9. Hand tighten the packing follower (key 10). Use a wrench to increase tightness by turning the follower an additional 60 degrees.
4. Fisher enhanced ENVIRO-SEAL Packing (Figure 9): Carefully insert each piece in exact order as shown in Figure 9. Tighten the packing follower (key 10) until the Belleville springs are compressed. This will be signaled by a significant increase in resistance. Back off the follower 1/8 to 1/4 turn. A gap of approximately 1.5 mm / 1/16 in. between the packing follower and the bonnet will ensure the packing is seated properly.
5. For Optional NOLEEK Bellows Seal Packing (Figure 8): Insert each piece in the exact order shown in the illustration. Tighten the packing follower (key 10) until it shoulders on the bonnet (key 8). This will compress the packing springs (key 7) to provide constant stem sealing throughout packing life.

3.4 Actuator and Valve Body Reassembly

1. Insert a new valve body gasket (key 49) and install the bonnet assembly (key 8). For NPS 1/2 to 1 valves, tighten the nuts (key 12) to a torque of 9.5 to 17.6 N•m / 7 to 13 lbf•ft; NPS 1-1/2 to 2 valves, tighten nuts (key 12) to a torque of 21.7 to 42.0 N•m / 16 to 31 lbf•ft.
2. Place the actuator yoke over the stem (key 5). While tilting the actuator back, drop the yoke drive nut (key 9) over the stem (key 5). Run the locknuts (key 27) and the travel indicator (key 58), down as far as possible and counter tighten the locknuts (key 27) to lock.

See the Fisher Baumann Actuator Instruction Manual ([D103352X012](#)) for reassembly and bench range adjustment.

NOTICE

When assembling or disassembling the valve, do not turn the valve stem while the plug is in contact with the valve seat. This can damage the seating surface very quickly.

WARNING

To avoid personal injury or equipment damage due to possible sudden shifting or falling of the valve assembly, do not lift the valve assembly by the handwheel.

Section 4: Parts

4.1 Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name and desired material using the following parts tables.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and could cause personal injury and property damage.

Special Fisher enhanced ENVIRO-SEAL Packing Note

The Fisher enhanced ENVIRO-SEAL PTFE packing system is suitable for 100 ppm environmental applications on services up to 51.7 bar / 750 psig and process temperatures ranging from -46 to 232°C / -50 to 450°F.

For non-environmental applications, this packing system offers excellent performance at the same temperature range up to the maximum valve working pressure.

Temperature limits apply to packing arrangements only. Complete valve assembly temperature limits may differ. Refer to appropriate pressure/ temperature ratings.

Section 1: Introduction

The Fisher Baumann 24000SB Barstock Control Valve (Figures 1 and 2) is recommended for low flow, high pressure, industrial control applications.

1.1 Scope of the Manual

This instruction manual includes installation, maintenance and parts information for the Fisher Baumann 24000SB barstock control valve.

WARNING

Do not install, operate or maintain Fisher Baumann 24000SB control valves without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Figure 1. 24000SB Control Valve with 32 Actuator

x0567

Figure 2. Fisher Baumann 24000SB Control Valve with Flanges and Extension Bonnet**⚠ WARNING**

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

⚠ WARNING

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

NOTE

The acronym of CWP may appear on the nameplate. CWP (Cold Working Pressure) denotes the pressure rating at normal ambient temperature. A normal ambient temperature range being -4 to +100°F / -20 to +38°C.

WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

WARNING

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

1.2 Education Services

Emerson's Education Services

Phone: 800-338-8158

Email: education@emerson.com

emerson.com/en/final-control/services/valve-training

Section 2: Maintenance

WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out under pressure when removing the packing hardware or packing rings or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTE

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

WARNING

Avoid personal injury or property damage by thoroughly cleaning the line of all dirt, welding chips, scale, oil or grease and other foreign material. Failure to do so could result in parts damage, malfunction of the control valve or loss of control of the process.

Section 3: Installation

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated by the arrow cast on the valve body.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. In case of a heat-insulated installation, insulate the valve body only, not the bonnet.

WARNING

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation. The valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

3.1 Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.
2. Use 6.4 mm / 1/4 in. O.D. tubing or equivalent for all air lines. If air line exceeds 8 m / 25 ft in length, 9.5 mm / 3/8 in. tubing is preferred. Air lines must not leak. Air pressure not to exceed 2.5 bar / 35 psig.

3.2 Disassembly

WARNING

If there is evidence of process fluid under pressure leaking from the joint, retighten the valve body/joint nuts. Return to the Warning at the beginning of the Maintenance section to ensure proper steps have been taken to isolate the valve and relieve process pressure.

 CAUTION

- **When assembling or disassembling the valve, do not turn the valve stem while the plug is touching the valve seat. This will damage the valve's seating surfaces.**
- **When adjusting the valve stem, do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem and cause damage to the packing in the valve. Instead, counter-tighten the two locknuts (key 27) on the stem (key 5). This will allow you to turn the stem by turning the locknuts (key 27) with a wrench.**
- **When placing the valve in a vise, do not clamp the rounded sides of the valve. This will distort the shape of the casting and will ruin the valve.**

Actuator Removal

Access to the internal components of the valve body can be accomplished with the actuator removed. For actuator maintenance see the Fisher Baumann Pneumatic Actuator Instruction Manual (D103352X012).

Air-to-Close Actuators

1. Disconnect the air supply to the actuator and remove the air tubing.
2. Loosen the drive nut (key 9) and then remove the plug and stem (keys 4 and 5) assembly by holding the actuator stem still while unthreading the plug and stem assembly counterclockwise.
3. Remove the stem locknuts (key 27), travel indicator (key 58) and yoke drive nut (key 9).
4. Remove the actuator from the valve.

Air-to-Open Actuators

1. Using flexible tubing, apply sufficient air pressure to the actuator to lift the plug off the seat.
2. Loosen the drive nut (key 9) and then remove the plug and stem (keys 4 and 5) assembly by holding the actuator stem still while unthreading the plug and stem assembly counterclockwise.
3. Remove the stem locknuts (key 27), travel indicator (key 58) and yoke drive nut (key 9).
4. Remove the actuator from the valve.
5. Disconnect the air supply to the actuator and remove the air tubing.

Valve Body Disassembly

1. After removing the actuator, unscrew the bonnet (key 8) and plug and stem (keys 4 and 5) from valve body (key 1). A new body gasket (key 49) should be installed each time the valve is disassembled.
2. Loosen the packing spring load by removing the packing follower (key 10).
Remove the plug and stem assembly by pulling it out through the bottom of the bonnet (key 8) while rotating the stem (key 5). This will help prevent damage to the packing components.

NOTE

Handle the parts carefully to avoid damaging the seating and guiding surfaces. Wipe the parts with a clean soft cloth and examine for signs of wear or damage.

3. Use a seat ring tool made according to the dimensions in Figure 3 and Table 1 to remove the seat ring (key 2) as follows:
 - a. Insert the tool into the valve body. Be certain the tool lugs are engaged in the corresponding recesses in the seat ring.
 - b. Use a 1/2 in. drive breaker bar or impact wrench having sufficient torque capability to remove the seat ring. Seat ring installation torque is provided in Table 2 for reference. Connect the breaker bar or impact wrench and if needed, a impact-rated extension bar, to the square drive of the seat ring tool.
 - c. Remove the seat ring (key 2) from the valve body. Make sure the seat ring tool is held at a right angle to the seat ring during removal to prevent the tool from disengaging from the lugs of the seat ring.
 - d. Inspect parts for wear or damage that would prevent proper operation of the valve body.
 - e. For Fisher Baumann 151 trim (Figure 7) unscrew the seat subassembly (key 51) with a 5/8 in. socket wrench. When reassembling, hand tighten the subassembly (key 51) and then rotate 1/8 of a turn with the 5/8 in. socket to lock in place.

NOTE

If changing to Fisher Baumann 151 trim, for correct flow characteristics, be sure the valve is reversed in the pipeline so that flow direction is flow-to-close.

- f. For Fisher Baumann 177 trim (Figure 8) unscrew the retainer nut (key 24) using a 3/4 in. socket wrench. Remove the gland (key 23) and insert (key 25). Replace the insert (key 25), making sure that the tapered portion faces up. If replacement of the housing (key 26) is required, use a 5/8 in. socket wrench.

Figure 3. Seat Ring Tool Dimensions

Table 1. Seat Ring Tool Dimensions (see Figure 3)

1. Male end used for trim 151.177 and port diameters 0.25 and 0.375.
2. Female end used for port diameters 0.8125.

3.3 Lapping the Valve Seat

If valve seat leakage becomes excessive, it may be necessary to lap the valve seat.

Lapping is the process of mating the valve plug to the seat ring, with an abrasive to produce a close fit. When valve seat leakage becomes excessive, lapping becomes necessary. The plug and seat ring seating surfaces should be free of large scratches or dents and the contact surface of the seats should be as narrow as possible.

1. Use a good quality lapping compound with a mixture that contains 280 to 600 grit. Apply at several spots around the plug seating surface. Replace the plug and stem carefully in the bonnet.
2. Install the bonnet (key 8) into the valve body, without gasket and hand tighten. The bonnet will serve as a guide during the lapping operation.
3. Lap the valve by applying a slight pressure on the stem and rotate the stem in short oscillating strokes approximately 8 to 10 times or until you see an even and complete lap line. The plug should be intermittently lifted and turned 90 degrees while lapping to keep the plug and seat ring concentric.
4. Clean the valve seat and plug (key 4) thoroughly when lapping is complete, removing all traces of lapping compound.

3.4 Replacing Packing

Refer to Figure 4 and the standard and optional packing constructions (Figure 9) to determine the packing that has been preinstalled in your valve.

1. Disassemble the valve as directed earlier. Remove the locknuts (key 27) and indicator disk (key 58) and turn the plug stem (key 5) out through the packing box. Remove the packing follower (key 10). Push out the old packing (key 14) by working from the underside of the bonnet (key 8).
2. Standard Spring Loaded PTFE V-Ring Packing (Figure 4): Carefully insert each piece in exact order shown in Figure 9. Tighten the packing follower (key 10) until it shoulders on the bonnet (key 8). This will compress the packing spring (key 6) to enable constant stem sealing throughout packing life.
3. Molded Graphite Ribbon Packing (Figure 9): Carefully insert each piece in exact order shown in Figure 9. Hand tighten the packing follower (key 10). Use a wrench to increase tightness by turning the follower an additional 60 degrees.
4. Fisher enhanced ENVIRO-SEAL™ Packing (Figure 9): Carefully insert each piece in exact order as shown in Figure 9. Tighten the packing follower (key 10) until it shoulders on the bonnet, then back off 1/4 turn. This will compress the Belleville spring (key 17) to ensure constant stem sealing is seated properly throughout the packing life.

3.5 Actuator and Valve Body Reassembly

1. Insert a new valve body gasket (key 49) and install the bonnet assembly (key 8).
2. Place the actuator yoke over the stem (key 5). While tilting the actuator back, drop the yoke drive nut (key 9) over the stem (key 5). Run the locknuts (key 27) and the travel indicator (key 58), down as far as possible and counter tighten the locknuts (key 27) to lock.

Carefully position the actuator over the stem (key 5), lift the plug stem and turn the plug stem (key 5) into the actuator stem as far as it will go before adjusting the bench range. See the following instruction manual (Fisher Baumann Actuator Instructions, [D103352X012](#)) for reassembly and bench range adjustment.

CAUTION

When assembling or disassembling the valve, do not turn the valve stem while the plug is in contact with the valve seat. This can damage the seating surface very quickly.

WARNING

To avoid personal injury or equipment damage due to possible sudden shifting or falling of the valve assembly, do not lift the valve assembly by the handwheel.

Section 4: Parts

4.1 Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name and desired material using the following parts tables.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and could cause personal injury and property damage.

Section 5: Special Fisher enhanced ENVIRO-SEAL Packing Note

The Fisher enhanced ENVIRO-SEAL PTFE packing system is suitable for 100 ppm environmental applications on services up to 51.7 bar / 750 psig and process temperatures ranging from -46 to +232°C / -50 to +450°F.

For non-environmental applications, this packing system offers excellent performance at the same temperature range up to the maximum valve working pressure.

Temperature limits apply to packing arrangements only. Complete valve assembly temperature limits may differ. Refer to appropriate pressure/ temperature ratings.

Reference the Fisher Packing Selection Guidelines for Sliding-Stem Valves Bulletin ([D101986X012](#)).

Section 1: Introduction

The Fisher Baumann 24003 3-way control valve (Figure 1) is ideally suited for control of flow and temperature where mixing or diverting service is required.

1.1 Scope of the Manual

This instruction manual includes installation, maintenance and parts information for the Fisher Baumann 24003 3-way control valve.

WARNING

Do not install, operate or maintain Fisher Baumann 24003 3-way control valves without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Figure 1. Fisher Baumann 24003 3-Way Valve

STAINLESS STEEL 3-WAY VALVE WITH 32 ACTUATOR

W7598

⚠ WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

⚠ WARNING

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

NOTE

The acronym of CWP may appear on the nameplate. CWP (Cold Working Pressure) denotes the pressure rating at normal ambient temperature. A normal ambient temperature range being -4 to +100°F / -20°C to +38°C.

⚠ WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

⚠ WARNING

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

1.2 Education Services

Emerson's Education Services

Phone: 800-338-8158

Email: education@emerson.com

emerson.com/en/final-control/services/valve-training

Section 2: Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out under pressure when removing the packing hardware or packing rings or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTE

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

** WARNING**

Avoid personal injury or property damage by thoroughly cleaning the line of all dirt, welding chips, scale, oil or grease and other foreign material. Failure to do so could result in parts damage, malfunction of the control valve or loss of control of the process.

Section 3: Installation

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated for either mixing or diverting service (see Table 1).
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. In case of a heat-insulated installation, insulate the valve body only, not the bonnet.

** WARNING**

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation. The valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

3.1 Air Piping

1. For an air-to-extend actuator (air-to-close Port L), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open Port L) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.
2. Use 6.4 mm / 1/4 in. O.D. tubing or equivalent for all air lines. If air line exceeds 8 m / 25 ft in length, 9.5 mm / 3/8 in. tubing is preferred. Air lines must not leak. Air pressure not to exceed 2.5 bar / 35 psig.

⚠ CAUTION

When assembling or disassembling the valve, do not turn the valve stem while the plug is touching the valve seat. This can damage the valve's seating surface very quickly.

When adjusting the valve stem, do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem and cause damage to the packing in the valve. Instead, counter-tighten the two locknuts (key 27) on the stem (key 5). This will allow you to turn the stem by turning the locknuts (key 27) with a wrench.

3.2 Disassembly

⚠ WARNING

When placing the valve in a vise, clamp the flat end faces of the valve. Do not try to clamp the rounded sides of the valve. This will distort the shape of the casting and damage the valve internals.

1. Mount the valve in a vise.
2. Remove the actuator, stem locknuts (key 27), travel indicator (key 58) and yoke drive nut (key 8). See the Fisher Baumann Pneumatic Actuators Instruction Manual (D103352X012).
3. Unscrew the bonnet (key 3) by turning in a counterclockwise direction from the valve body (key 1). Lift the bonnet up and off the plug and stem assembly (key 4).
4. Unscrew the lower seat ring retainer (key 5) from the valve body (key 1) and remove the plug and stem assembly (key 4) (see Figure 2). Wipe the parts with a clean soft cloth and examine for signs of wear.

3.3 Lapping the Valve Seat

If valve seat leakage becomes excessive, it may be necessary to lap the valve seat.

Lapping is the process of mating the valve plug to the seat ring, with an abrasive to produce a close fit. When valve seat leakage becomes excessive, lapping becomes necessary. The plug and seat ring seating surfaces should be free of large scratches or dents and the contact surface of the seats should be as narrow as possible.

1. Use a good quality lapping compound with a mixture that contains 280 to 600 grit. Apply at several spots around the plug seating surface.

2. Replace the plug and stem assembly (key 4) through the bottom of the valve body (key 1) and screw in the lower seat ring retainer (key 5).
3. Place the bonnet (key 3) loosely into the valve body to serve as a guide during the lapping operation.
4. Rotate the plug and stem assembly (key 4), applying light pressure to the plug/seat mating surface.
5. Lap as little as possible. Excessive lapping will shoulder the seat ring and will not improve the seating. Repeat for the second seating surface.
6. Clean the valve seats and plug thoroughly when the lapping is complete.

3.4 Replacing Packing

Refer to Figure 2 and the standard and optional packing constructions (Figures 3, 4 and 5) to determine the packing that has been preinstalled in your valve.

1. Mount the valve in a vise.
2. Remove actuator, stem locknuts (key 27), travel indicator (key 58), packing follower (key 7) and yoke drive nut (key 8) per the Fisher Baumann Pneumatic Actuators Instruction Manual (D103352X012).
3. Unscrew the bonnet (key 3) by turning in a counterclockwise direction from the valve body (key 1). Lift the bonnet up and off the plug and stem assembly (key 4). Push the old packing out from the underside of the bonnet (key 3).
4. Standard Spring Loaded PTFE V-Ring Packing (Figures 2 and 3): Carefully insert each piece in exact order shown in Figure 3. Turn the packing follower (key 7) until it shoulders on the bonnet (key 3). This will compress the packing spring (key 9) to enable constant stem sealing throughout packing life.
5. Molded Graphite Ribbon Packing (Figure 4): Carefully insert each piece in exact order shown in Figure 4. Hand tighten the packing follower (key 7). Use a wrench to increase tightness by turning the nut an additional 60 degrees.
6. Fisher enhanced ENVIRO-SEAL Packing (Figure 5): Carefully insert each piece in exact order as shown in Figure 5. Tighten the packing follower (key 7) until the Belleville springs are compressed. This will be signaled by a significant increase in resistance. Back off the follower 1/8 to 1/4 turn. A gap of approximately 1/16 inch between the packing follower and the bonnet will ensure packing is seated properly.

CAUTION

Overtightening the packing may prevent stem movement and valve operation and result in equipment damage or loss of control of the process.

3.5 Reassembly

1. Place the plug and stem assembly (key 4) into the valve body (key 1) from the lower port and screw in the lower seat ring retainer (key 5).
2. Place the bonnet (key 3) over the stem and tighten in place.
3. Insert the packing kit by following steps 4, 5 or 6 of Replacing Packing shown previously.
4. Place the actuator yoke over the stem and bonnet. While tilting the actuator back to allow access to the top of the stem, place the yoke drive nut (key 8) over the stem.
5. Next, turn one locknut (key 27) onto the stem, turning it down as far as possible. Place the travel indicator (key 58) over the stem and then turn the second locknut (key 27) down against the travel indicator (key 58). Counter turn the locknuts to tighten securely.

See the Fisher Baumann Pneumatic Actuators Instruction Manual ([D103352X012](#)) for bench range adjustment.

CAUTION

When assembling or disassembling the valve, do not turn the valve stem while the plug is in contact with either seat. This can damage the seating surface very quickly.

Section 4: Parts

4.1 Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name and desired material using the following parts tables.

⚠ WARNING

Use only genuine Fisher™ replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and could cause personal injury and property damage.

Section 5: Special Fisher enhanced ENVIRO-SEAL Packing Note

The Fisher enhanced ENVIRO-SEAL PTFE packing system is suitable for 100 ppm environmental applications on services up to 51.7 bar / 750 psig and process temperatures ranging from -46 to +232°C / -50 to +450°F.

For non-environmental applications, this packing system offers excellent performance at the same temperature range up to the maximum valve working pressure.

Temperature limits apply to packing arrangements only. Complete valve assembly temperature limits may differ. Refer to appropriate pressure/ temperature ratings.

Reference Fisher Packing Selection Guidelines for Sliding-Stem Valves Bulletin (D101986X012).

4.2	Parts List	8

Section 1: Introduction

1.1 Scope of the Manual

This instruction manual includes installation, maintenance and parts information for the Fisher Baumann 26000 corrosion resistant control valve.

WARNING

Do not install, operate or maintain Fisher Baumann 26000 control valves without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

1.2 Description

The Fisher Baumann 26000 Corrosion Resistant Control Valve (Figure 1) features a flangeless wafer valve body. The 316 stainless steel flangeless body and thru-hole wafer design allows for installation between plastic pipeline flanges without risk of gasket leakage. This same valve body, fully pressurized, retains an all wetted PTFE interior resulting in a solid mechanical structure.

Figure 1. Fisher Baumann 26000 Control Valve

Email: education@emerson.com
emerson.com/en/final-control/services/valve-training

1.4 Safety Precautions

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

WARNING

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are, you should contact your [Emerson sales office](#) for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

NOTE

The acronym of CWP may appear on the nameplate. CWP (Cold Working Pressure) denotes the pressure rating at normal ambient temperature. A normal ambient temperature range being -4 to +100 °F / -20 to +38°C.

⚠ WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise, take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

⚠ WARNING

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

Section 2: Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out under pressure when removing the packing hardware or packing rings or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTE

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

⚠ WARNING

Avoid personal injury or property damage by thoroughly cleaning the line of all dirt, welding chips, scale, oil or grease and other foreign material. Failure to do so could result in parts damage, malfunction of the control valve or loss of control of the process.

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation, the valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

Section 3: Installation

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated by the arrow cast on the valve body.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. In case of a heat-insulated installation, insulate the valve body only, not the bonnet.

⚠ CAUTION

The PTFE valve body insert protrudes slightly beyond both sides of the valve body (key 1); it is highly recommended that the included PTFE encapsulated line flange adapter gaskets (key 21) be utilized. (Refer to Figures 2, 3 and 4).

3.1 Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.
2. Use 6.4 mm / 1/4 in. O.D. tubing or equivalent for all air lines. If air line exceeds 8 m / 25 ft in length, 9.5 mm / 3/8 in. tubing is preferred. Air lines must not leak. Air pressure not to exceed 2.5 bar / 35 psig.

3.2 Packing Adjustments

Refer to Figures 2, 3 and 4.

Should seat leakage or leakage by the bonnet (key 8) occur, try to retighten the internal packing (key 17) by disconnecting the air line to the actuator, loosen the hex clamp nut (key 12) and turn the bonnet (key 8) clockwise into the valve body (key 1). This rotation will compress the packing (key 17) around the plug and stem assembly (key 4) and against the valve body interior. Retighten the hex clamp nut (key 12) and recheck for leakage.

Should the valve stem packing (key 14) need to be adjusted, turn the packing follower (key 10) clockwise to tighten or counterclockwise to loosen.

3.3 Disassembly

Significant wear or contamination may require replacement of the plug or seals. Proceed as follows:

1. Loosen the yoke clamp nut (key 9) and disconnect the actuator (see appropriate actuator instructions).
2. Loosen the packing follower (key 10) and the hex clamp nut (key 12).
3. Unscrew and remove the bonnet (key 8) from the valve body (key 1).
4. Remove the packing (key 17) from the valve body (key 1) by flowing air into port A. This will drive the V-ring packing seals and plug out of the top opening of the valve body.

CAUTION

The PTFE valve body insert protrudes slightly beyond both sides of the valve body (key 1); it is highly recommended that the included PTFE encapsulated line flange adapter gaskets (key 21) be utilized.

3.4 Reassembly and Calibration

1. Lay out all parts and clean the valve body thoroughly.
2. Hold the valve body (key 1) upside down, see Figure 5.
3. Insert the lower (half round) packing ring.

NOTE

The flat side should rest in the bottom of the housing bore.

4. Insert the first packing V-ring with the V opening facing the lower ring. Tip the ring slightly to prevent the ring from hanging up at the corner of the outlet port, see Figure 5.
5. For $C_v < 1.0$, insert a spacer ring (key 3) with the V opening towards first packing ring. Note: The cross hole must line up with the hole B in a radial direction and within 1/16 in. in the vertical direction. The spacer ring (key 3) is not required in $C_v = 2.5$ or $C_v = 4.2$.

6. Insert the remainder of the packing V-rings (key 17) as shown, one at a time. Tip each ring slightly to ease installation.
7. Move the valve body (key 1) right-side up and clamp in a vise or test fixture, using the line flange adapter gaskets (key 21).
8. Screw the hex clamp nut (key 12) all the way onto the lower thread of the bonnet (key 8).
9. Screw the bonnet seal (key 50) all the way onto the lower thread of the bonnet (key 8) until it touches the nut (key 12).
10. Lubricate the lower bonnet thread with anti-seize lubricant and insert the valve plug and stem assembly (key 4) into the bonnet (key 8).
11. Screw the bonnet (key 8) with the plug and stem assembly (key 4) loosely into the valve body (key 1).
12. Push the stem all the way down until the plug is fully seated.
13. Install the valve body in the test fixture or between a pair of appropriate mating line flanges.
14. Apply 50 psi air pressure to the fixture or the flange connected to valve port A and connect port B to a flow meter or bubble indicator (tube in water).
15. For $C_v < 1.0$, slowly screw the bonnet (key 8) into the valve body with a 1-1/4 in. wrench until the air flow stops completely. Push the valve stem up and down several times and repeat the leakage test. For $C_v > 1.0$, screw the bonnet (key 8) down until it touches the packing and then turn an additional 180 degrees.

NOTE

The force to pull up or push down the stem should not exceed 25 lbs.

16. Close off air flow leaving port B and pull up the stem. This will pressurize all parts of the valve body.
17. Apply leak detection fluid or soap solution to the thread between the valve body and bonnet (key 8). There should be no leakage.
18. Hold the bonnet in place and tighten the nut (key 12) firmly (this will compress the bonnet seal (key 50)).
19. Install the secondary packing kit [packing spring (key 6), washer (key 16), stem packing rings (key 14), packing spacer (key 20) and packing follower (key 10)] into the bonnet as shown in Figure 6. Tighten by rotating the packing follower (key 10) nut clockwise.
20. Attach the actuator to the bonnet. Turn the actuator to thread the actuator stem onto the valve stem until the yoke touches the shoulder of the bonnet.
21. Lock the drive nut (key 9), see Figures 2, 3 and 4.
22. Apply 4 to 5 psi to the actuator for air-to-open or 13 to 14 psi for air-to-close.
23. With 50 psi air applied to port A, counter tighten the jam nuts (key 27) and slowly turn the valve plug and stem assembly (key 4) clockwise to thread it into the actuator stem. Stop and lock the stem with the jam nut (key 27) when port B shows some minimum flow.
24. Adjust the zero position of the travel indicator to the present position of the travel indicator disk (key 58).

25. Reduce air pressure to 3 psi for air-to-open or increase air pressure to 15 psi for air-to-close. For $C_v < 1.0$, there should be no seat leakage (Class VI). For $C_v > 1.0$, the allowed leakage is Class IV. If leakage is noted, loosen the jam nuts (key 27) and turn the plug and stem assembly (key 4) further into the valve bonnet (key 8).
26. At the lowest actuator travel position, the indicator disk (key 58) shall be at least 0.040 in. below the zero travel position. If not, move the stem (key 4) further into the bonnet (key 8) and recalibrate the travel indicator.
27. Check the valve travel for a full 1/2 in. from the zero point on the indicator scale.
28. Check the dead band of the actuator. The difference between the signal to move the stem up and the signal to move stem down shall not exceed 2 psi. If it does exceed 2 psi, the secondary packing (key 14) is too tight.
29. See appropriate actuator instructions to set the travel stops. (Refer to illustrations in the appropriate actuator instruction manual to determine what type of stops are being used).
30. Attach and calibrate the positioner.

NOTE

Travel should commence from the zero travel indicator mark at 3.2 psi / 4.3 mA air-to-open or at 14.8 psi / 19.7 mA air-to-close. The flow should enter only through the lower port A to help energize the V-ring packing set (key 17).

Section 4: Parts

4.1 Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name and desired material using the following parts tables.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and could cause personal injury and property damage.

4.2 Parts List

NOTE

Contact your [Emerson sales office](#) for Part Ordering information.

Table 1. Parts List

Key No.	Description
1	Valve Body with PTFE Insert, Cv= 0.001 - 1.0
	Valve Body with PTFE Insert, Cv= 2.5
	Valve Body with PTFE Insert, Cv= 4.2
3*	Spacer (Cv = .001 to 1.0 ONLY)
4*	Plug and Stem Subassembly, Cv=0.001
	Plug and Stem Subassembly, Cv=0.005
	Plug and Stem Subassembly, Cv=0.01
	Plug and Stem Subassembly, Cv=0.02
	Plug and Stem Subassembly, Cv=0.05
	Plug and Stem Subassembly, Cv=0.1
	Plug and Stem Subassembly, Cv=0.2
	Plug and Stem Subassembly, Cv=0.4
	Plug and Stem Subassembly, Cv=0.8
	Plug and Stem Subassembly, Cv=1.0
	Plug and Stem Subassembly, Cv=2.5
	Plug and Stem Subassembly, Cv=4.2
8	Bonnet
	Bonnet, Extension
9	Drive Nut (Yoke)
10	Packing Follower
12	Hex Clamp Nut
14*	Secondary Packing Kit, V-ring, Standard
17*	Primary Packing, Cv < 1.0 (6 rings)
	Primary Packing, Cv = 2.5 (6 rings)
	Primary Packing, Cv = 4.2 (9 rings)
21	Line Flange Adapter Gaskets, qty 2
27	Jam Nut, qty 2
50	Bonnet Seal
58	Travel Indicator
*Recommended spare parts

Section 4: Parts Ordering

8

Section 1: Introduction

The Fisher Baumann 51000 control valve (Figure 1) is optimally designed for demanding low flow control and is a perfect fit where space is at a premium. This compact package provides the connection integrity of flanged body globe valves, while being significantly lighter and easier to install.

1.1 Scope of the Manual

This instruction manual includes installation, maintenance and parts information for the Fisher Baumann 51000 control valve and Fisher Baumann 16 actuator.

⚠ WARNING

Do not install, operate or maintain Fisher Baumann 51000 control valves without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

93.3	178	207	200	2580	3000
149	161	200	300	2330	2910
176	154	196	350	2235	2850

Section 2: Installation

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

WARNING

When ordered, the valve configuration and construction materials were selected to meet particular pressure, temperature, pressure drop and controlled fluid conditions. Responsibility for the safety of process media and compatibility of valve materials with process media rests solely with the purchaser and end-user. Because some valve body/trim material combinations are limited in their pressure drop and temperature range capabilities, do not apply any other conditions to the valve without first contacting your [Emerson sales office](#).

NOTE

The acronym of CWP may appear on the nameplate. CWP (Cold Working Pressure) denotes the pressure rating at normal ambient temperature. A normal ambient temperature range being -4 to +100°F / -20 to +38°C.

⚠ WARNING

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

NOTICE

To avoid damaging valve seating surfaces, make sure the adjacent piping is free of pipe scale, welding slag and any other potentially damaging material.

1. Before installing the valve in the pipeline, inspect the valve body to be certain it is free of foreign material and thoroughly clean the line of all dirt, welding chips, scale, oil or grease and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated by the arrow.
3. A three-valve bypass permits removal of the control valve from the line without shutting down the system.
4. In case of a heat-insulated installation, insulate the valve body only, not the bonnet.

Section 3: Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out under pressure when removing the packing hardware or packing rings or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTE

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

3.1 Actuator Removal

Refer to Figures 2, 3, 7 and 8.

1. For air-to-open actuators, lift actuator travel with air to lessen tension on the upper clamp nut (key 10).

NOTE

For air-to-close, this is NOT required.

2. Gently tap the upper clamp nut (key 10). With slight downward pressure on top of the actuator, unscrew the upper clamp nut (key 10) completely.
3. The Fisher Baumann 16 actuator assembly must be unscrewed from the stem adapter (key 26).

3.2 Plug and Packing Replacement

Refer to Figures 2 and 3.

NOTICE

When adjusting the valve stem, do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem and cause damage to the packing in the valve.

1. For valves supplied with Fisher Baumann 16 actuators, remove the travel indicator disc (key 58). With the hex jam nuts (key 27) still tight, loosen the stem adapter (key 26) from the stem adapter nut (key 31) and unthread the stem adapter (key 26) from the plug stem (key 4).

For valves with rated C_v 's less than 1.0, unscrew the packing nut (key 11) and gently pull the plug (key 4) out through the top of the bonnet (key 6).

For valves with rated C_v 's greater than or equal to 1.0, follow the valve disassembly instructions to first remove the bonnet (key 6) before removing the plug (key 4).

2. Inspect or replace the packing (key 9) and the stem guide (key 8).
3. Inspect the valve plug (key 4) for wear or particle accumulation.

3.3 Valve Disassembly

Refer to Figures 2 and 3.

NOTE

The actuator must be removed from the valve body before valve body disassembly.

1. Remove the bonnet hex nuts (key 7) and lift the bonnet (key 6) off the valve body (key 1), which may include the packing (key 9) and plug assembly (key 4). [For alloy valve bodies, lift the bonnet flange (key 34) off from the bonnet (key 6) and then lift the bonnet (key 6) off the valve body (key 1)].
2. Remove the bonnet gasket (key 5) and replace.
3. The cage subassembly (key 3) can be removed by unscrewing with a flat screwdriver, using the outer screw slot and lifting out of the valve body (key 1). The cage subassembly should be inspected and cleaned with water or an approved solvent.

For valves with rated C_v 's greater than or equal to 1.0, remove and inspect the plug guide (key 33) for wear. Replace if necessary. Replacement of the entire assembly will be necessary if excessive leakage or wear has occurred in service.

NOTE

The seat cage gasket (key 2) must be replaced when the cage subassembly (key 3) has been removed. The seat cage will appear oblong. This is to prevent loosening of the soft seat.

Figure 2. Fisher Baumann 51000 Valve Body Subassembly, NPS 1/4 Soft Seat

E1230

Soft Seat

Figure 3. Fisher Baumann 51000 Valve Body Subassembly, NPS 1/2 Alloy Valve Body Integral (Metal) Seat

E1232

3.4 Valve Reassembly

1. Place the cage gasket (key 2) and cage subassembly (key 3) in the valve body (key 1).
2. Tighten the cage (key 3) hand tight plus 1/8 of a turn. (For valves with rated C_v 's greater than or equal to 1.0, insert the plug guide (key 33)).
3. Place the seat plug (key 4) into the valve body (key 1).
4. Place the bonnet gasket (key 5) into the valve body (key 1). Look at the bonnet (key 6) and valve body (key 1) for correct bonnet orientation.
5. Place the bonnet (key 6) onto the valve body (key 1) and secure with the hex nuts (key 7). For alloy valve bodies, place the bonnet (key 6) onto the valve body (key 1), then place the bonnet flange (key 34) over the bonnet—confirm correct orientation—then secure with the hex nuts (key 7).

DO NOT TIGHTEN AT THIS POINT.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

Instruction Manual

D103365X012

51000 Valve

July 2026

6. Install the stem guide (key 8) and packing kit (key 9) on the plug stem (key 4) in the proper order (as shown in Figure 4).
7. Carefully press into the top of the bonnet (key 6) making sure each part is seated properly.
8. Install packing rings over the stem one at a time. Use the packing follower nut (key 11) to push each packing ring in individually to avoid jamming.
9. With all required packing (key 9) in place, tighten the packing follower nut (key 11) until it becomes stiff.

DO NOT OVERTIGHTEN THE PACKING FOLLOWER (key 11).

10. Now tighten the hex nuts (key 7)

Section 4: Parts

4.1	Parts Ordering.....	7
-----	---------------------	---

Section 1: Introduction

The Fisher Baumann 81000 control valve (Figure 1) is excellent for throttling of liquid or gaseous media. A low friction mechanical force-amplifying mechanism is used to reduce the travel of the pneumatic or electric actuators. This mechanism moves the closure diaphragm precisely against the valve orifice to throttle or stop the passing fluid.

1.1 Scope of the Manual

This instruction manual includes installation, maintenance and parts information for the Fisher Baumann 81000 control valve.

WARNING

Do not install, operate or maintain Fisher Baumann 81000 control valves without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

AND FISHER FIELDVUE™ DVC2000
DIGITAL VALVE CONTROLLER**

W9847

⚠ WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

⚠ WARNING

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

NOTE

The acronym of CWP may appear on the nameplate. CWP (Cold Working Pressure) denotes the pressure rating at normal ambient temperature. A normal ambient temperature range being -4 to +100°F / -20 to +38°C.

⚠ WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

⚠ WARNING

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

Emerson's Education Services

Phone: 800-338-8158

Email: education@emerson.com

emerson.com/en/final-control/services/valve-training

Section 2: Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out under pressure when removing the packing hardware or packing rings or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTE

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

⚠ WARNING

Avoid personal injury or property damage by thoroughly cleaning the line of all dirt, welding chips, scale, oil or grease and other foreign material. Failure to do so could result in parts damage, malfunction of the control valve or loss of control of the process.

Section 3: Installation

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease and other foreign material. A micron size filter is recommended upstream of the valve.
2. Install the valve so that the controlled fluid will flow through the valve body in the direction selected from the guidelines shown below.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. A pressure gauge may be installed in the 1/8 inch port in the bolted bonnet (see Figure 4). This gauge tells when leakage or breakage of the diaphragm has occurred.

⚠ WARNING

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation, the valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

3.1 Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case. See Figures 2 and 3.
2. Use 6.4 mm / 1/4 in. O.D. tubing or equivalent for all air lines. If the air line exceeds 8 m / 25 ft in length, 9.5 mm / 3/8 in. tubing is preferred. Air pressure should not to exceed 2.5 bar / 35 psig.

3.2 Flow Direction

There are two possible ways to pass fluid through the valve (see Figures 6 and 7). In the flow-to-open mode, fluid enters from Port A to Port B. In the flow-to-close mode, fluid enters from Port B to Port A.

Each flow direction has its advantages and disadvantages. The following guide will make a selection easier.

Use Flow From Port B to A

- In vacuum applications with spring P/N 81168Z, vacuum on down stream.
- With fluids that have a tendency to cavitate.
- In applications where inlet pressure is low and no seat spring can be tolerated.
- When self-cleaning operation is required for removal of solid particles in flow stream.

Use Flow From Port A to B

- When valve has to fail close in case of bursting or damage to the sealing diaphragm.

3.3 Disassembly

WARNING

If there is evidence of process fluid under pressure leaking from the joint, retighten the valve body/joint nuts and return to the Warning at the beginning of the Maintenance section to provide proper steps have been taken to isolate the valve and relieve process pressure.

1. Remove the actuator by unscrewing the yoke drive nut (key 9) and lifting off the complete actuator assembly. This keeps the actuator assembly intact and calibrated to the factory setting. Refer to actuator instructions.
2. Remove the bolts (key 13) and lift the bonnet yoke assembly (key 2) with the diaphragm (key 5) and O-ring (key 15) from the valve body (key 1). Lift out the spring (key 6).
3. Remove the O-ring (key 15) and diaphragm (key 5). Wipe with a clean soft cloth and examine for wear.
4. Inspect the valve body sealing surfaces. Refer to the Lapping the Valve Seat procedure in this instruction manual.

3.4 Lapping the Valve Seat

If valve seat leakage becomes excessive, it may be necessary to lap the valve seat.

1. Use a good quality lapping compound with a mixture that contains 280 to 600 grit. Apply at several spots around the plug seating surface (refer to Figure 5).
2. Thoroughly lap the valve body on a flat, preferably cast iron, surface plate.
3. Clean the seats thoroughly after lapping.
4. Inspect the diaphragm (key 5) and replace if necessary.

3.5 Bonnet Maintenance

1. Remove the actuator by unscrewing the yoke drive nut (key 9) and lifting off the complete actuator assembly. Hold the flattened portions of the bonnet yoke (key 2) in a vise and unscrew the valve bonnet (key 8) using a 2-1/4 in. wrench. Remove and inspect the bearing cartridge assembly (key 4) and O-ring (key 49).
2. Reinsert the parts, O-ring (key 49) and bearing cartridge assembly (key 4), ensuring the bearings extend below the side plate of the bearing cartridge assembly (key 4) and contact the piston subassembly (key 3). With the plunger (key 10) removed, screw the bonnet (key 8) onto the yoke (key 2). There should be no binding or galling. Tighten the bonnet with a wrench until there is metal-to-metal contact.
3. Insert the plunger (key 10) and push it in and out. The piston subassembly (key 3) should travel easily up and down.

3.6 Calibration

1. Reassemble the valve by inserting the spring (key 6), O-ring (key 15) and diaphragm (key 5) into the valve body.
2. Replace the bonnet yoke assembly (key 2) and install the bolts (key 13) and tighten. Add the jam nut (key 27) and travel indicator disk (key 58) to the plunger (key 10). Line up the plunger (key 10) in the bearing cartridge assembly (key 4). Screw the actuator onto the plunger (key 10) until the actuator yoke touches the bonnet (key 8). Lock the actuator with the drive nut (key 9).
3. To prevent damage to the plunger (key 10) or the bearing cartridge subassembly (key 4), be sure the hex jam nut (key 27) is not tightened against the travel indicator (key 58).

CAUTION

To prevent damage to the plunger (key 10) or bearing cartridge subassembly (key 4), be sure the hex jam nut (key 27) is not tightened against the travel indicator (key 58).

3.7 Do Not Attempt to Rotate the Plunger (key 10)

1. For an air-to-retract actuator (air-to-open). Apply 6.9 bar / 100 psi air pressure (or N2) to the normal valve inlet. Apply 0.2 bar / 3.2 psi air signal to the actuator. Use 0.07 bar / 1 psi signal to the actuator if the inlet pressure exceeds 6.9 bar / 100 psi. If the valve leaks, slowly turn the actuator stem counterclockwise. This will move the plunger (key 10) down until leakage is below 1 cc/min. Lock the plunger (key 10) in position with the jam nut (key 27). Calibrate the travel scale and check for 12.7 mm / 1/2 in. valve travel; apply a 1.04 bar / 15 psi signal. Reverse the signal; the plunger should move in the opposite direction with less than 0.014 bar / 0.2 psi signal change.
2. For an air-to-extend actuator (air-to-close), use the same procedure as in step one, except apply 0.88 bar / 12.8 psi to the actuator to calibrate the shut off position.

Section 4: Parts

4.1 Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name and desired material using the following parts tables.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and could cause personal injury and property damage.

83000 Sanitary Angle Valve
with Baumann 16 Actuator

83000 Sanitary Angle Valve
with FIELDVUE™ DVC2000
Digital Valve Controller

Introduction

The Baumann 83000 Sanitary angle control valve (figure 1) features a packless design and is intended for laboratory flow rates as low as 0.001 liters per minute (l/m) with a Cv range of 0.00001 to 1.2. This innovative design also allows for clean-in-place (CIP) and sanitize-in-place (SIP) procedures and is self-draining. Meets 3-A sanitary standards for design and fabrication.

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for the Baumann 83000 sanitary angle control valve.

Do not install, operate, or maintain Baumann 83000 control valves without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

⚠ WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) or Local Business Partner for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

⚠ WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

Educational Services

For information on available courses for the Baumann 83000 sanitary angle control valve, as well as a variety of other products, contact:

Emerson Automation Solutions

Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Note

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

⚠ WARNING

Avoid personal injury or property damage by thoroughly cleaning the line of all dirt, welding chips, scale, oil or grease, and other foreign material. Failure to do so could result in parts damage, malfunction of the control valve or loss of control of the process.

Installation

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease, and other foreign material. A micron size filter is recommended upstream of the valve.
2. Install the valve so that the controlled fluid will flow through the valve body in the direction selected from the guidelines shown below.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. A pressure gauge or other telltale connection should be installed in the 1/8 inch port in the bolted yoke (see figure 7). This gauge tells when leakage or breakage of the diaphragm has occurred.

⚠ WARNING

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation, the valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case. See figures 4 and 5.
2. Use 6.4 mm (1/4 inch) O.D. tubing or equivalent for all air lines. If the air line exceeds 8 m (25 ft) in length, 9.5 mm (3/8 inch) tubing is preferred. Air lines must not leak. Air pressure should not exceed 2.5 bar (35 psig).

Flow Direction

There are two possible ways to pass fluid through the valve: in the Flow-to-Open mode, fluid enters through Port B and flows to Port A (see figure 2). In the Flow-to-Close mode, fluid enters through the port leading into the chamber or body bowl, Port A to port B. See figure 2 for port identification.

Each flow direction has its advantages and disadvantages. The following guide will make a selection easier.

Use Flow to Open: Port B to A

- When the valve has to fail close in case of bursting or damage to sealing diaphragm.
- When the valve must drain from inlet to outlet. (Valve mounted with actuator horizontal.)

Use Flow to Close: Port A to B

- In vacuum applications, vacuum on down stream.
- With fluids that have a tendency to cavitate.
- When a self-cleaning operation is required for removal of solid particles in the flow stream.

Disassembly

⚠ WARNING

If there is evidence of process fluid under pressure leaking from the joint, retighten the valve body/joint nuts and return to the Warning at the beginning of the Maintenance section to provide proper steps have been taken to isolate the valve and relieve process pressure.

1. Remove the actuator by unscrewing the yoke drive nut (key 9) and lifting off the complete actuator assembly. This keeps the actuator assembly intact and calibrated to the factory setting. Refer to actuator instructions.
2. Remove the bolts (key 13) and lift the bonnet yoke assembly (key 2) with the diaphragm (key 5) and O-ring (key 15) from the valve body (key 1).

3. Remove the O-ring (key 15) and diaphragm (key 5). Wipe with a clean soft cloth and examine for wear.
4. Inspect the valve body sealing surfaces. Refer to the Lapping the Valve Seat procedure in this instruction manual.

Lapping Sealing Surfaces

If valve leakage becomes excessive, it may be necessary to lap the sealing surfaces.

1. Use a good quality lapping compound with a mixture that contains 280 to 600 grit. Apply at several spots around the valve body sealing surfaces (refer to figure 6).
2. Thoroughly lap the valve body (key 1) on a flat, preferably cast iron, surface plate.
3. Clean the seats thoroughly after lapping.
4. Inspect the diaphragm (key 5) and replace if necessary.

Bonnet Maintenance

1. Remove the actuator by unscrewing the yoke drive nut (key 9) and lifting off the complete actuator assembly. Hold the flattened portions of the bonnet yoke (key 2) in a vise and unscrew the valve bonnet (key 8) using a 2-1/4 inch wrench. Remove and inspect the bearing cartridge assembly (key 4) and O-ring (key 49).
2. Reinsert the parts, O-ring (key 49) and bearing cartridge assembly (key 4), ensuring the bearings extend below the side plate of the bearing cartridge assembly (key 4) and contact the piston subassembly (key 3). With the plunger (key 10) removed, screw the bonnet (key 8) onto the yoke (key 2). There should be no binding or galling. Tighten the bonnet with a wrench until there is metal-to-metal contact.
3. Insert the plunger (key 10) and push it in and out. The piston subassembly (key 3) should travel easily up and down.

Valve Body to Bonnet Assembly

1. Place the diaphragm (key 5) in the bonnet yoke (key 2) cavity.
2. Place the O-ring (key 15) on the diaphragm (key 5) in the cavity. This should hold the diaphragm in place while assembling.
3. Place the bonnet assembly onto the valve body (key 1).
4. The locking screw (key 13) will thread through the bonnet yoke (key 2) and tighten into the valve body (key 1).

Calibration

1. Reassemble the valve by inserting the O-ring (key 15) and diaphragm (key 5) into the valve body.
2. Replace the bonnet yoke assembly (key 2) and install the bolts (key 13) and tighten. Add the jam nut (key 27) and travel indicator disk (key 58) to the plunger (key 10). Place the drive nut (key 9) over the plunger (key 10). Line up the plunger (key 10) in the bearing cartridge assembly (key 4). Screw the actuator onto the plunger (key 10) until the actuator yoke touches the bonnet (key 8). Lock the actuator with the drive nut (key 9).

Do Not Attempt to Rotate the Plunger (key 10)

CAUTION

To prevent damage to the plunger (key 10) or bearing cartridge subassembly (key 4), be sure the hex jam nut (key 27) is not tightened against the travel indicator (key 58).

1. For an air-to-retract actuator (air-to-open/fail closed). Apply 6.9 bar (100 psi) air pressure (or N2) to the normal valve inlet A. Apply 0.2 bar (3.2 psi) air signal to the actuator. Add 0.07 bar (1 psi) signal to the actuator if the inlet pressure exceeds 6.9 bar (100 psi). If the valve leaks, slowly turn the actuator stem counterclockwise. This will move the plunger (key 10) down until leakage is below 1 cc/min. Lock the plunger (key 10) in position with the jam nut (key 27). Calibrate the travel scale and check for 12.7 mm (1/2 inch) valve travel; apply a 1.04 bar (15 psi) signal. Reverse the signal; the plunger should move in the opposite direction with less than 0.014 bar (0.2 psi) signal change.
2. For an air-to-extend actuator (air-to-close/fail open), use the same procedure as in step one, except apply 0.88 bar (12.8 psi) to the actuator to calibrate the shut off position.

Note

For Baumann 16 actuator ONLY. For inlet pressures exceeding 10.6 bar (150 psi), 12.77 mm (NPS 1/2) or 20.7 bar (300 psi), 6.35 mm (NPS 1/4), use a positioner or I/P transducer with an output pressure of 0.07 - 1.2 bar (1-17 psi) (ASME-FCI Standard 87-2) to ensure the valve will close properly.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name, and desired material using the following parts tables.

WARNING

Use only genuine Fisher™ replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

The Baumann 84000 sanitary control valve (figures 1, 2, and 3) is designed to satisfy the stringent demands of the pharmaceutical and biotechnology industries. These valves are in compliance with 3-A Sanitary Standards, Inc. requirements.

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for the Baumann 84000 sanitary control valve.

Do not install, operate, or maintain Baumann 84000 control valves without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

W9840

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) or Local Business Partner for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

WARNING

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

Maintenance

WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Note

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

Flow Direction

The preferred flow direction for self-draining is shown in figures 8 and 9.

Installation

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease, and other foreign material. A micron size filter is recommended upstream of the valve.
2. Install valve so that the controlled fluid will flow through the valve body in the direction selected in figures 8 and 9. The leak detection port should be located at the lowest point in the installed position.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.
4. To detect if leakage or breakage of the diaphragm has occurred, a pressure gauge may be installed in the 1/8 NPT port (key 14) in the bonnet, see figures 4, 5, and 6.

WARNING

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation, the valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.

2. Use 6.4 mm (1/4 inch) O.D. tubing or equivalent for all air lines. If the air line exceeds 8 m (25 ft) in length, 9.5 mm (3/8 inch) tubing is preferred. Air lines must not leak. Air pressure should not exceed 2.5 bar (35 psig).

Valve Body Removal

Reference figures 4, 5, and 6.
(Not Required For Actuator Reversal)

For field replacement of the diaphragm (key 8), follow steps 1 through 4 below.

Note

Do not squeeze the valve body in a vise.

1. For fail-closed action (air-to-open), stroke the actuator up to take pressure off from the diaphragm pushing against seat. For fail-open action (air-to-close), there is no need to stroke actuator.
2. Remove the bonnet screws (key 18) for NPS 1 valves or the clamp (key 11) for NPS 1-1/2 or 2 valves.
3. Lift the bonnet assembly (key 2) with the actuator from the valve body (key 1).
4. Once disassembled; for fail-closed action ONLY, release pressure from the actuator to be able to unscrew the diaphragm, for fail-open action you must pressurize the actuator to unscrew the diaphragm. This is the only action required for inspection or cleaning.
5. Stroke the actuator down to exert some pressure and remove the diaphragm (key 8) by unscrewing the diaphragm (key 8) from the compressor (key 5). Remove the bonnet O-ring (key 15) (NPS 1-1/2 and 2 valves only). Wipe the diaphragm (key 8) with a clean soft cloth and examine for wear.
6. Inspect the valve body sealing surfaces. If valve leakage becomes excessive, replacement of the diaphragm (key 8) may be necessary.

Actuator Removal

To remove the actuator, unscrew the drive nut (key 9) and loosen the jam nuts (key 27). Unscrew the piston stem (key 3) from the actuator stem.

CAUTION

Avoid personal injury or property damage from sudden release of pressure or bursting of parts. Remove the actuator before attempting to disassemble the valve.

Bonnet Disassembly

Actuator Removed

Remove the diaphragm (key 8) and the bonnet O-ring (key 15) (NPS 1-1/2 and 2 valves only) per instructions under the previous Valve Body Removal section. Proceed as follows:

1. Turn over the bonnet assembly (key 2).

2. Pry out the retaining ring (key 7) using a small flat screwdriver.
3. Remove the wave springs (key 6), compressor (key 5) and drive mechanism (key 4).
4. Push out the piston-stem assembly (key 3). Clean and replace as required.

Note

For NPS 1-1/2 & 2 valves, measure the gap between the free ends of the clamp (key 11) and return to this position upon reassembly to minimize change in zero calibration.

Bonnet Reassembly

Actuator Removed

For correct orientation of the sub-assemblies to the bonnet refer to figure 7, exploded view.

1. Insert the piston stem assembly (key 3) into the bonnet (key 2).
2. Orient the drive mechanism as shown in figure 7.
3. Verify that the machined surfaces at the end of the rectangular plates are in full contact with the machined recess inside the bonnet (key 2).
4. **IMPORTANT:** Verify that the recessed roller bearings in the drive mechanism (key 4) rest against the flats of the piston stem assembly (key 3).
5. Install the compressor (key 5) per figures 4, 5, and 6 with the flat side resting against the extended roller bearings.
6. Drop the wave springs (key 6) into place, prongs down; the NPS 1 valve requires two wave springs. The NPS 1-1/2 and 2 valves require three wave springs. Oppose the spring opening 180 degrees when installing the wave springs.
7. Retain all parts by installing the retaining ring (key 7) into the bonnet groove.
8. The gap in the retaining ring (key 7) should align with the crest of the wave spring (key 6).
9. Push down on the bonnet assembly to drive the piston stem assembly (key 3) firmly into the drive mechanism (key 4) to provide some tension.
10. Insert the O-ring (key 15) (NPS 1-1/2 and 2 valves only), so that it rests on the retaining ring (key 7).
11. Lubricate the screw thread and the cone of the diaphragm (key 8) with sterile food grade lubricant.
12. Screw the diaphragm (key 8) onto the compressor (key 5) snugly. **DO NOT OVERTIGHTEN.**
13. Place the complete bonnet assembly onto the valve body (key 1).
 - a. The diaphragm (key 8) rim must fit into the body groove for proper centering.
 - b. The NPS 1 bolted flange configuration should be tightened for metal-to-metal contact between the flange and the valve body. Be sure to use 45 lbf•ft when tightening the valve body bolts on the NPS 1 valve.
 - c. For NPS 1-1/2 and 2 valves, apply the clamp (key 11) and tighten the nut gradually, checking for an even amount of PTFE over the valve body, between the bonnet and clamp, for proper centering.
 - d. The gap between the clamp ends should be approximately 1/2 inch or less for proper diaphragm compression. **DO NOT OVERTIGHTEN THE CLAMP.**
 - e. Examine through port B to ensure the diaphragm is centered on the seating area.

Valve Calibration

After the valve is assembled per the previous instructions, install the properly configured actuator (reference the Baumann Pneumatic Actuators instruction manual, [D103352X012](#)), making sure to engage the piston stem (key 3) as much as possible into the actuator stem. Tighten the drive nut (key 9). (Refer to figures 8 and 9 for the preferred flow direction.)

Calibration of Fail-Close (Air-to-Open) Actuator

1. Apply 50 psi air or nitrogen to port B. Apply 3 psi air signal to the actuator.
 - a. Slowly turn the piston stem assembly (key 3) out of the actuator stem until flow stops.

Note

When adjusting the valve stem, do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem. Instead, counter-tighten the two locknuts on the stem together. This will allow you to turn the stem by turning the locknuts with a wrench.

- b. Check the valve for leaks with 50 psi air under the diaphragm (port B). Leakage should be less than 1 cc/min. The valve should start to leak or low flow at a minimum pressure signal to the actuator. If it takes more than minimum pressure to open, then screw the piston stem assembly (key 3) further into the actuator stem. If the valve is not tight at 3 psi signal, screw the piston stem assembly (key 3) out of the actuator stem further. Next, calibrate Zero on the travel indicator scale with a minimum pressure signal to the actuator. Check for full travel at the maximum pressure signal. If the leak persists, increase the force on the clamp (key 11) to compress the diaphragm (key 8) by tightening the clamp nut. For NPS 1 valves, tighten the bolts (key 18) on the bonnet flange (key 11) using 45 lbf•ft.

CAUTION

The stem should travel below zero by approximately 1/16 to 1/8 inch after the signal is decreased below 3 psi. IF THE VALVE DOES NOT CLOSE PROPERLY, INCREASE THE CLAMP COMPRESSION AROUND THE DIAPHRAGM (key 8) by tightening 1/2 turn. DO NOT tighten to the point that the diaphragm wrinkles.

Calibration of Fail-Open (Air-to-Close) Actuator

2. Apply 50 psi air pressure or nitrogen to port B. Apply 15 psi air signal to actuator.
 - a. Slowly turn the piston stem assembly (key 3) out of the actuator stem until flow stops.
 - b. Check the valve for leaks with 50 psi air under the diaphragm (port B). Leakage should be less than 1 cc/min. The valve should start to leak or low flow at a maximum pressure signal to the actuator. If it takes more than the maximum pressure to open, then screw the piston-stem (key 3) further into the actuator stem. If the valve is not tight at 15 psi signal, screw the piston-stem (key 3) out of the actuator stem further. Next, calibrate Zero on the travel indicator scale with maximum pressure signal to the actuator. Check for full travel at minimum pressure signal. If the leak persists, increase the force on the clamp (key 11) to compress the diaphragm (key 8) by tightening the clamp nut. For NPS 1 valves, tighten the bolts (key 18) on the bonnet flange (key 11) using 45 lbf•ft.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

Instruction Manual

D103370X012

84000 Valve

June 2017

CAUTION

The stem should travel below zero by approximately 1/16 to 1/8 inch after the signal is increased above 15 psi. IF THE VALVE DOES NOT CLOSE PROPERLY, INCREASE THE CLAMP COMPRESSION AROUND THE DIAPHRAGM (key 8) by tightening 1/2 turn. DO NOT tighten to the point that the diaphragm wrinkles.

Note

When using a Baumann 32 actuator with dual stops or a Baumann 54 actuator, the shaft collar (key 25) can also be set at intermediate positions to provide a minimum opening valve travel stop.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name, and desired material using the following parts tables.

⚠ WARNING

Use only genuine Fisher™ replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Figure 1. Baumann 85000 Sanitary Pinch Valve

Introduction

Baumann 85000 sanitary pinch valves (figure 1) are intended for use with pharmaceutical grade tubing.

Note

The maximum temperature and process pressure is dependent upon the type/grade of process tubing selected by the user.

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for the 85000 sanitary pinch valve.

Do not install, operate, or maintain 85000 pinch valves without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

⚠ WARNING

To avoid personal injury, keep fingers clear of tubing passage when flexible tubing is not installed in the valve body.

⚠ WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury. Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) or Local Business Partner for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

⚠ WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

Maintenance

WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

WARNING

To avoid personal injury, keep fingers clear of tubing passage when flexible tubing is not installed in the valve body.

Assembly

1. Place four captive screws in the valve body.
2. Set two bushings in the bonnet, one after the other, so that the top bushing is flush with the top of the bonnet.
3. Place the stem in the bushing, as shown in figure 2, to ensure free movement.
4. Align the valve body and bonnet and tighten the screws to a maximum torque of 2.6 N•m (23 lbf•in).
5. Install the actuator assembly with the yoke clamp nut, two hex nuts, and the indicator washer. Ensure that the indicator washer is aligned.
6. Align the actuator with the valve body, tighten the yoke clamp nut and lock down nut.

WARNING

To avoid personal injury or property damage, do not attempt to perform any work on a valve while the system is in operation. The valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.
2. Use 6.4 mm (1/4 inch) O.D. tubing or equivalent for all air lines. If air line exceeds 8 m (25 ft) in length, 9.5 mm (3/8 inch) tubing is preferred. Air lines must not leak. Air pressure is not to exceed 2.5 bar (35 psig).

Installation

1. Loosen all four captive screws and remove the valve body.
2. Install flexible tubing; ensure the spherical closure member is retracted.
3. Align the valve body with the bonnet and retighten the four captive screws to a maximum torque of 2.6 N•m (23 lbf•in).

Disassembly

CAUTION

When assembling or disassembling the valve, do not turn the valve stem. Turning the valve stem will affect calibration.

CAUTION

When adjusting the valve stem, do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem, and cause damage to the bushings in the valve. Instead, counter-tighten the two locknuts on the stem together. This will allow you to turn the stem by turning the locknuts with a wrench.

Actuator Removal

Access to the internal components of the valve body can be accomplished with the actuator removed. For actuator maintenance see the following instruction manual (Baumann Actuator Instructions, [D103352X012](#)).

Air-to-Close Actuators

1. Disconnect the air supply to the actuator and remove the air tubing.
2. Loosen the drive nut and then remove the plug and stem assembly by holding the actuator stem still while unthreading the plug and stem assembly counterclockwise.
3. Remove the stem locknuts, travel indicator, and yoke drive nut.
4. Remove the actuator from the valve.
5. Disconnect the air supply to the actuator and remove the air tubing.

Air-to-Open Actuators

1. Using flexible tubing, apply sufficient air pressure to the actuator to lift the plug off the seat.
2. Loosen the drive nut and then remove the plug and stem assembly by holding the actuator stem still while unthreading the plug and stem assembly counterclockwise.
3. Remove the stem locknuts, travel indicator, and yoke drive nut.
4. Remove the actuator from the valve.
5. Disconnect the air supply to the actuator and remove the air tubing.

Actuator and Valve Body Reassembly

1. Place the actuator yoke over the stem. While tilting the actuator back, drop the yoke drive nut over the stem. Run the locknuts, and the travel indicator down as far as possible and counter tighten the locknuts to lock.

Carefully position the actuator over the stem, lift the plug stem, and turn the plug stem into the actuator stem as far as it will go before adjusting the travel.

Travel Adjustment

With the actuator mounted on the valve, turn the stem until a 4 mm (0.16 inch) clearance is left between the spherical surface of the plunger and the bottom surface of the valve body against which the flexible tubing will be compressed.

This 4mm (0.16 inch) clearance is appropriate for most types/grades of tubing, but if leakage is experienced it may be necessary to reduce this gap.

Setting the clearance too small may result in reduced tubing life.

WARNING

To avoid personal injury or equipment damage due to possible sudden shifting or falling of the valve assembly, do not lift the valve assembly by the handwheel.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the part name using the following parts tables.

⚠ WARNING

Use only genuine Fisher™ replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Table 1. Parts List

Component	Part Number	Quantity
Bonnet	GE48200X012	1
Valve Body	GE48199X012	1

W9823

**RECOMMENDED MOUNTING POSITION
FOR SELF-DRAINING**

W9824

**WITH FIELDVUE™ DVC2000
DIGITAL VALVE CONTROLLER**

Introduction

The Baumann 87000 Flexsleeve control valve (figure 1) with tri-clamp body connections and polished flow contours, is excellent for throttling high purity liquid or gaseous media. The valve is suitable for repeated steam sterilization cycles with 35 psi maximum steam pressures. Assembly of valve body sections uses only two bolts allowing for ease of cleaning and inspection. A lower telltale port is provided. The valve will drain either horizontally or vertically with the actuator in the horizontal position. The operation is not affected by vacuum.

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for the Baumann 87000 sanitary control valve.

Do not install, operate, or maintain Baumann 87000 control valves without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is

important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

⚠ WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your Emerson sales office or Local Business Partner for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

⚠ WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.

- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Note

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

WARNING

Avoid personal injury or property damage by thoroughly cleaning the line of all dirt, welding chips, scale, oil or grease, and other foreign material. Failure to do so could result in damage to the seating and sealing surfaces of the valve and result in release of process materials.

Installation and Maintenance

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease, and other foreign material. A micron size filter is recommended upstream of the valve.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated by the arrow on the valve body.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.

WARNING

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation, the valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

Air Piping

Refer to figure 2.

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.

2. Use 6.4 mm (1/4 inch) O.D. tubing or equivalent for all air lines. If the air line exceeds 8 m (25 ft) in length, 9.5 mm (3/8 inch) tubing is preferred. For proper operation, air lines must not leak. Air pressure should not exceed 2.5 bar (35 psig).
3. Tri-clamp connections should line up properly to provide a tight seal.

CAUTION

Do not place the valve in a vise. This will damage the exterior of the valve body and possibly the end connections of the valve.

⚠ WARNING

If there is evidence of process fluid under pressure leaking from the joint, retighten the valve body/joint nuts. Return to the Warning at the beginning of the Installation and Maintenance section to ensure proper steps have been taken to isolate the valve and relieve process pressure.

Disassembly of Valve

Refer to figure 3.

1. Depressurize the pipeline and valve interior. Disconnect air lines from the positioner.
2. Loosen the tri-clamp connections and remove the valve from the line.
3. Remove the hex head cap screws (key 12) that secure the valve body to the lower bonnet (key 3) and the upper bonnet (key 2). Remove the upper bonnet, actuator and positioner from the valve. Be sure the ceramic ball (key 5) does not fall out of the assembly and get lost.
4. In order to remove the shaft (key 4), unscrew the alignment pin (key 15) and remove the retaining ring (key 11).

Reassembly of Valve

Refer to figures 3, 4, and 5.

1. Reassemble the valve in reverse order using the instructions above. The valve body is designed so it cannot be assembled improperly. Make sure the beveled edge of the anvil (key 8) points toward the ceramic ball (key 5). Make sure the tapered end of the sleeve bushing (key 6) also points towards the ceramic ball.
2. If the sleeve (key 7) seating surface is distorted, the sleeve should be replaced, or be rotated to use a new seating surface.
3. New O-rings (keys 9 and 50) should be installed after suitable lubrication (e.g. food grade) of the shaft O-ring (key 50).
4. Make sure the alignment pin (key 15) is tight and the shaft (key 4) moves easily.
5. Refer to separate instructions for the actuator (D103352X012) and positioner assembly and maintenance.
6. Place the actuator yoke over the shaft (key 4). While tilting the actuator back, drop the yoke drive nut (key 16) over the shaft (key 4). Run the locknut (key 27), and travel indicator (key 58) down as far as possible onto the shaft (key 4).
7. Carefully place the actuator yoke in a vertical position and thread the actuator stem onto the shaft, spin the actuator onto the shaft as far as it will go before adjusting the bench range. Refer to Baumann Pneumatic Actuators instruction manual, [D103352X012](#).

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name, and desired material using the following parts tables.

⚠ WARNING

Use only genuine Fisher™ replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Figure 6. Mode of Operation

E1296

Mode of Operation

As shown in figure 6, a flexible sleeve is inserted through the length of the valve and sealed between the valve body and bonnet by O-rings. The actuator-motivated valve stem has a tapered groove that pushes a ceramic ball against the inside of the sleeve and, thereby, the sleeve against a valve seat.

Figure 1. Baumann 89000 NPS 1/2 Sanitary Control Valve Shown with FIELDVUE™ DVC2000 Digital Valve Controller

W9850

Introduction

The Baumann 89000 sanitary control valve (figures 1 and 2) provides control solutions for sanitary and aseptic process systems. These valves meet FDA and USP CLVI standards. They are designed to drain freely from inlet to outlet. In sanitary and aseptic valve applications, the surface finish of all wetted parts is of the utmost importance and needs to be free of pits and cracks. The Baumann 89000 series valves meet all of these requirements.

The 89000 control valve covers a wide range of applications in many industries including food and beverage, biotechnology, pharmaceutical, and others where cleanliness and sterility are required. The valves are designed for easy maintenance and all parts in contact with the media are made of corrosion resistant S31603 stainless steel.

Figure 2. Baumann 89000 NPS 3 Sanitary Control Valve Shown with FIELDVUE DVC6200 Digital Valve Controller

W9851-2

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for the Baumann 89000 series sanitary control valve.

Do not install, operate, or maintain Baumann 89000 control valves without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

Educational Services

Safety Precautions

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

This valve is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the valve could result in parts damage, malfunction of the control valve or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) or Local Business Partner for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Depending on the actuator construction, it will be necessary to manage the pneumatic actuator spring pre-compression. It is essential to refer to the relevant actuator instructions in this manual to perform safe removal of the actuator from the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Note

Whenever a gasket seal is disturbed by removing or shifting gasketed parts, install a new gasket during reassembly. This provides a good gasket seal because the used gasket may not seal properly.

Installation

1. Before installing the valve in the pipeline, thoroughly clean the line of all dirt, welding chips, scale, oil or grease, and other foreign material.
2. Install the valve so the controlled fluid will flow through the valve body in the direction indicated. If you are not sure, reference Baumann bulletin 51.2:89SV, [D103346X012](#) or contact your [Emerson sales office](#) or Local Business Partner.
3. A three-valve bypass must be used to permit removal of the control valve from the line without shutting down the system.

⚠ WARNING

To avoid personal injury or property damage, do not attempt to do any work on a valve while the system is in operation, the valve must be isolated 100% from the active system and the isolated line voided of pressure and/or hazardous fluids.

Air Piping

1. For an air-to-extend actuator (air-to-close action), connect the actuating air pressure line to the 1/4 NPT opening in the upper diaphragm case. For an air-to-retract actuator (air-to-open action) connect the actuating air pressure line to the 1/4 NPT in the lower diaphragm case.
2. Use 6.4 mm (1/4 inch) O.D. tubing on type 20 and 9.6 mm (3/8 inch) on types 50, 50H, and 112 or equivalent for all air lines. If the air line exceeds 8 m (25 ft) in length, 9.5 mm (3/8 inch) tubing is preferred. Air lines must not leak. Air pressure not to exceed 6.9 bar (100 psig).

CAUTION

When assembling or disassembling the valve, do not turn the valve stem while the plug is touching the valve seat. This will damage the valve's seating surfaces.

When adjusting the valve stem, do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem, and cause damage to the O-ring seals in the valve. Instead, use a spanner or Allen wrench through the recessed holes on the stem (key 12). This will allow you to turn the stem.

Do not place valve in a vise. This can distort the shape of the valve.

CAUTION

Prior to performing maintenance on the valve, isolate the valve, vent the process pressure, and shut off supply and signal air lines to the actuator.

Disassembly

Actuator Removal

Access to the internal components of the valve body can be accomplished with the actuator removed.

Air-to-Close Actuators

1. Disconnect the air supply to the actuator (key 2) and remove the air tubing.
2. Loosen the upper body clamp (key 5) and then remove the plug and stem (key 12) by holding the actuator stem still while unthreading the plug and stem (key 12) counterclockwise.
3. Remove the stem locknut (key 8) and the upper body clamp (key 5) by sliding the yoke (key 4) and actuator assembly off from the plug and stem (key 12).
4. Carefully remove the actuator from the valve.

Air-to-Open Actuators

1. Using flexible tubing, apply sufficient air pressure to the actuator (key 2) to lift the plug and stem (key 12) off the valve seat/lower pipe connection (key 13).
2. Loosen the upper body clamp (key 5) and then remove the plug and stem (key 12) by holding the actuator stem still while unthreading the plug and stem (key 12) counterclockwise.
3. Remove the stem locknut (key 8) and the upper body clamp (key 5).

4. Carefully remove the actuator from the valve.

Valve Body Disassembly

89000A, Angle Valve Body

1. After removal of the actuator (key 2), the bonnet (key 10) should be visible. Slide the bonnet (key 10) out of the valve body assembly and off of the plug and stem (key 12). Be sure not to tear the O-ring seals.
2. Remove the plug and stem (key 12) from the valve body (key 1a).
3. Unthread the lower body clamp bolts and remove the bolts from the lower body clamp (key 7). Take the lower body clamp off of the valve body (key 1a) and the valve seat/lower pipe connection (key 13) from the valve body.
4. Carefully slide the valve seat/lower pipe connection (key 13) from the valve body (key 1a), being sure not to tear the O-ring seal.
5. Inspect all O-rings and sealing surface for signs of wear and scratches. Replace O-rings if needed.

89000I, Inline Valve Body

1. After removal of the actuator (key 2), the bonnet (key 10) should be visible. Slide the bonnet (key 10) out of the upper valve body (key 1b) and off of the plug and stem (key 12).
2. Remove the plug and stem (key 12) from the upper valve body (key 1b).
3. Unthread the middle valve body clamp bolts and remove the bolts from the middle body clamp (key 6). Take the middle body clamp (key 6) off and slide the lower body (key 1c) away from the upper body (key 1b). Be sure not to tear the O-ring seal.
4. Once the lower body (key 1c) has been removed, the valve seat (key 16) should be visible. Carefully slide the valve seat (key 16) from the upper valve body (key 1b), being sure not to tear the O-ring seal.
5. Carefully slide the lower valve body wall from the lower valve body (key 1c), being sure not to tear the O-ring seal.
6. Inspect all O-rings and sealing surfaces for signs of wear and scratches. Replace the O-rings if needed.

Replacing O-Ring Seals

Remove the old O-rings by hand or with an appropriate tool. Be sure not to scratch the sealing surfaces of the valve components. Replace the O-rings with care, being sure not to overstretch, tear, or twist the O-rings.

Valve Body Reassembly

Reverse the previous Valve Body Disassembly procedure. Be sure to take care and not damage the O-rings when pressing the valve body components back into place.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name, and desired material using the following parts tables.

⚠ WARNING

Use only genuine Fisher™ replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

The Baumann multiple-spring diaphragm actuators are powerful and compact devices designed to operate control valves, louvers, dampers or mechanical speed adjusting devices. The actuators can provide either direct air-to-extend action (ATE) or reverse air-to-retract action (ATR). When an ATE actuator is installed on a typical Baumann valve, it provides an air-to-close (ATC) or fail-open function. When an ATR actuator is installed, it provides an air-to-open (ATO) or fail-closed function. The design features exceptionally low hysteresis due to the absence of side loads imposed by misalignment of single coiled springs. The use of multiple springs also offers a substantially lower profile.

The units include zinc-plated, epoxy-coated steel diaphragm cases and an epoxy-coated ductile-iron yoke. Stainless steel diaphragm cases, actuator stems, and yokes are available for Baumann size 32 and 54 actuators. The Baumann size 16 actuator comes standard with a stainless steel yoke and epoxy-coated steel diaphragm case. All remaining metal parts are made of either stainless or zinc plated steel for optimum corrosion resistance.

All actuators are suitable for a standard ambient temperature range of -29 to 71 °C (-20 to 160 °F); for higher temperature service, an optional design is available, consult your [Emerson sales office](#).

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for Baumann pneumatic actuators.

Do not install, operate, or maintain Baumann actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your Emerson sales office before proceeding.

Design Notes

The same basic actuator may be configured in several ways. Variations may produce either a 7.9 mm (5/16 inch), 12.7 mm (1/2 inch), or 19.1 mm (3/4 inch) stroke. The spring tables list the nominal bench spring ranges. Each line in the table lists the high and low limits for the signal air pressure, measured in bar and pounds per square inch (psi). These signal pressures produce the rated stroke lengths when the actuator is not loaded. The signal air connections use 1/4 NPT fittings, and are located in both the lower (key 43) and upper (key 44) diaphragm cases. Use the lower connection for an air-to-retract (ATR) actuator and the upper connection for an air-to-extend (ATE) actuator. The signal air pressure must not exceed 2.4 bar (35 psi). Higher pressures may cause the diaphragm to leak.

Installation

⚠ WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

To avoid personal injury or property damage resulting from the bursting of pressure retaining parts, be certain the service conditions do not exceed either the valve body rating or the flange joint rating, or other limits given on the nameplate. Use pressure-relieving or pressure-limiting devices to prevent the service conditions from exceeding these limits.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section on page 6 in this manual.

NOTICE

Often, these types of actuators are attached to valves which include a stainless steel stem and valve seat. When assembling or adjusting the actuators, never turn the valve stem when the plug is touching the valve seat. If the two stainless steel parts rotate while they are touching, they can be damaged very easily.

When adjusting the valve stem (key 5), do not grip the stem directly with pliers or a wrench. This will damage the surface of the stem, and cause damage to the packing in the valve. Instead, counter-tighten the two locknuts (key 27) on the stem together. This will allow you to turn the stem by turning the locknuts with a wrench.

⚠ WARNING

Personal injury or equipment damage caused by sudden release of pressure or bursting of parts may result if the valve assembly is installed where service conditions could exceed the limits given in the product literature, the limits on the appropriate nameplates, or the mating pipe flange rating. Use pressure-relieving devices as required by government or accepted industry codes and good engineering practices. If you cannot determine the ratings and limits for this product, contact your [Emerson sales office](#) before proceeding.

Personal injury could result from packing leakage. The packing might require some readjustment to meet specific service conditions.

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem whether it be from air pressure on the diaphragm or compression in the actuator springs.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

Attaching an Air-to-Retract (ATR) Actuator to a Valve - Part 1

Follow these instructions when assembling the actuator to a valve or other device which provides a positive stop in one direction.

1. Before starting, identify and locate these parts on the valve assembly, figure 1: stem locknuts (key 27), travel indicator (key 58), bonnet (key 8), yoke drive nut (key 9), and plug and stem assembly (keys 4 and 5). Refer to the assembly instructions for the appropriate Baumann control valve.
2. Place the valve body (key 1) in a vise. Clamp the flat end faces of the valve. **DO NOT CLAMP THE SIDES OF THE VALVE.** This may distort the shape of the casting, and ruin the valve.
3. Begin to attach the actuator to the valve body, figures 1 and 2 through figure 14, depending on actuator type. The yoke drive nut (key 9) and travel indicator (key 58) must be removed from the valve body assembly. The hole at the bottom of the actuator yoke (key 17) should fit over the top of the valve stem (key 5). Tilt the top of the actuator back at an angle so you can access the top of the valve stem (key 5).
4. Position the drive nut (key 9) over the valve stem (key 5) with the flat side facing up. (The rounded side should face down, toward the top surface of the yoke.)
5. Thread the two locknuts (key 27) onto the valve stem (key 5). Turn both nuts down as far as possible. Lock nuts together using two wrenches to counter-tighten them. By turning the locked nuts with a wrench, you can turn the valve stem without damaging the surface of the stem.
6. Place the travel indicator (key 58) over the valve stem (key 5).
7. If applicable, loosen shaft collar (key 25), figure 6, and turn clockwise until it reaches the bottom of the actuator stem (key 26).
8. Apply anti-seize compound to the first few threads of the valve stem (key 5). Turn the actuator counterclockwise to locate the first thread on the stem. Thread stem into the actuator a half turn.
9. Apply 1 bar (15 psi) to the signal air port in the lower diaphragm case (key 43). The bottom of the yoke will drop down and touch the top of the valve bonnet (key 8).
10. By hand, tighten the drive nut (key 9).
11. Using a wrench on the counter-tightened nuts (key 27), turn the stem (key 5) up until you feel a resistance.
12. Using a hammer and punch, tighten the drive nut (key 9).
13. Next, make the bench range adjustment. See the next section.

Bench Range Adjustment Air-to-Retract (ATR) Actuator

This adjustment sets the valve so that it opens and closes at the correct signal air pressures. On an air-to-retract actuator, when the pressure reaches the low end of the range, the valve should just begin to open. Once the bench range has been set correctly, the valve should be completely open when it receives full signal air pressure, and the valve travel should also be correct. The spring tables list the possible pressure ranges for different valve configurations. The signal pressure at the low end of the range is dependent on the springs used in the actuator. In order to make this adjustment, you will need an adjustable source of compressed air ranging from 0 to 1 bar (0 to 15 psi) for Baumann 16 and 32 actuators, 0 to 1.4 bar (0 to 20 psi) for Baumann 54 and 70 actuators with a 1/4 NPT external connector.

1. Connect the air source to the signal air port in the lower diaphragm case (key 43). Begin at 0 bar (0 psi) and gradually increase the pressure. Notice the pressure at the point when the valve stem (key 5) just begins to move.
 - a. If the pressure at this point is too low (lower than the recommended bench initials shown in the spring tables), the actuator and stem assembly should be longer. Turn the valve stem (key 5) out of the actuator stem (key 26) 1/2 turn.
 - b. If the pressure at this point is too high, the actuator and stem assembly should be shorter. Turn the valve stem (key 5) into the actuator stem (key 26) 1/2 turn.
2. Adjust the length of the valve stem (key 5) as described above. Always turn the valve stem (key 5) using a wrench on the two counter-tightened nuts (key 27). Never turn stems while the plug is on the seat.

3. You may have to repeat steps 1 and 2 several times to get the correct setting.

NOTICE

Remember that the valve stem (key 5) cannot be allowed to turn against the valve seat when the two parts are touching. Before you make any adjustment, apply 1 bar (15 psi) to the actuator. This will lift the valve stem away from the seat, and help prevent damage.

Attaching an Air-to-Retract (ATR) Actuator to a Valve - Part 2

1. Once the bench range has been adjusted correctly, you can complete the assembly. Apply 1 bar (15 psi) to the signal port on the actuator.
2. Using two wrenches, unlock the two counter-tightened nuts (key 27). There are flats on the actuator stem (key 26). Hold these flats with a wrench and, one at a time, turn each nut up as far as possible. Counter-tighten the two nuts together again.
3. Reduce the air pressure to 0 bar (0 psi). Loosen the screws (key 57) which hold the travel indicator scale (key 56) in place. Set the scale so the lowest line matches the level of the travel indicator washer.
4. Set the air pressure to the high end of the valve's operating pressure. The travel indicator should move through the full rated travel of 7.9, 12.7, or 19.1 mm (5/16, 1/2, or 3/4 inch).

Note

The shaft collar (key 25), if applicable, can be set at intermediate positions to provide a minimum opening valve travel stop following calibration.

Attaching an Air-to-Extend (ATE) Actuator to a Valve - Part 1

Follow these instructions when assembling the actuator to a valve or another device which provides a positive stop in one direction. (Baumann 70 actuator is ATR only.)

1. Before starting, identify and locate these parts on the valve assembly, figure 1: stem locknuts (key 27), travel indicator (key 58), bonnet (key 8), yoke drive nut (key 9), and plug and stem assembly (keys 4 and 5). Refer to the assembly instructions for the appropriate Baumann control valve.
2. Place the valve body (key 1) in a vise. Clamp the flat end faces of the valve. **DO NOT CLAMP THE SIDES OF THE VALVE.** This may distort the shape of the casting, and ruin the valve.
3. Begin to attach the actuator to the valve body. The yoke drive nut (key 9) and travel indicator (key 58) must be removed from the valve body assembly. The hole at the bottom of the actuator yoke (key 17) should fit over the top of the valve stem (key 5). Tilt the top of the actuator back at an angle so you can access the top of the valve stem (key 5).
4. Position the drive nut (key 9) over the valve stem (key 5) with the flat side facing up. (The rounded side should face down, toward the top surface of the yoke.)
5. Thread the two locknuts (key 27) onto the valve stem (key 5). Turn both nuts down as far as possible. Lock nuts together using two wrenches to counter-tighten them. By turning the locked nuts with a wrench, you can turn the valve stem without damaging the surface of the stem.
6. Place the travel indicator (key 58) over the valve stem (key 5).

7. If applicable, loosen shaft collar (key 25, figure 6) and turn clockwise until it reaches the bottom of the actuator stem (key 26).
8. Apply anti-seize compound to the first few threads of the valve stem (key 5). Place the actuator over the top of the valve bonnet (key 8). The yoke of the actuator will make contact with the top of the bonnet (key 8). Extend the valve stem (key 5) into the actuator stem (key 26). Turn the stem (key 5) until it comes to a stop, then back off 1/2 turn.
9. By hand, tighten the drive nut (key 9).
10. Using a wrench on the counter-tightened nuts (key 27), turn the stem (key 5) up until you feel a resistance.
11. Using a hammer and punch, tighten the drive nut (key 9).
12. Next, make the bench range adjustment. See the next section.

Bench Range Adjustment Air-to-Extend (ATE) Actuator

This adjustment sets the valve so that it opens and closes at the correct signal air pressures. On an air-to-extend actuator, when the pressure reaches the high end of the range, the valve should be completely closed. Once the bench range has been set correctly, the valve should be completely open when it receives the low reading for the signal air pressure, and the valve travel should also be correct. The spring tables list the possible pressure ranges for different valve configurations. The signal pressure at the high end of the range is dependent on the springs used in the actuator. In order to make this adjustment, you will need an adjustable source of compressed air ranging from 0 to 1 bar (0 to 15 psi) for Baumann 16 and 32 actuators, or 0 to 1.4 bar (0 to 20 psi) for Baumann 54 and 70 actuators with a 1/4 NPT external connector.

1. Connect the air source to the signal air port in the upper diaphragm case (key 44). Gradually increase the pressure toward the high rating listed in the appropriate spring table. Notice the pressure at the point when the valve is fully seated, and the valve stem (key 5) stops moving.
 - a. If the pressure at this point is too high, the actuator and stem assembly should be longer. Turn the valve stem (key 5) out of the actuator stem (key 26) 1/2 turn.
 - b. If the pressure at this point is too low, the actuator and stem assembly should be shorter. Turn the valve stem (key 5) into the actuator stem (key 26) 1/2 turn.
2. Adjust the length of the valve stem (key 5) as described in the last step. Always turn the valve stem (key 5) using a wrench on the two counter-tightened nuts (key 27).

NOTICE

Remember that the valve stem (key 5) cannot be allowed to turn against the valve seat when the two parts are touching. Before you make any adjustment, be certain that there is no air signal to the actuator.

3. You may have to repeat steps 1 and 2 several times to get the correct setting.

Attaching an Air-to-Extend (ATE) Actuator to a Valve - Part 2

1. Once the bench range has been adjusted correctly, you can complete the assembly. Apply 0 bar (0 psi) to the signal port on the actuator.
2. Using two wrenches, unlock the two counter-tightened nuts (key 27). There are flats on the actuator stem (key 26). Hold the flats with a wrench and, one at a time, turn each nut up until you feel a resistance. Counter-tighten the two nuts together again.
3. Apply 1 bar (15 psi) to the signal port. Loosen the screws (key 57) which hold the travel indicator scale (key 56) in place. Set the scale so the lowest line matches the level of the travel indicator (key 58).

4. Apply 0 bar (0 psi). The travel indicator (key 58) should move through the full rated travel of 7.9, 12.7, or 19.1 mm (5/16, 1/2, or 3/4 inches).

Spring Replacement, Changing Bench Range

The springs inside the actuator can be replaced or changed if necessary. This is necessary if you want to change the bench range - the range of pressures over which the actuator is designed to operate. The spring tables list the possible spring combinations. To use the tables, identify the stroke and the pressure range for the new valve configuration. This will tell you the part number and the quantity of the springs needed.

Figures 2 and 3 for Baumann 16 actuators, figures 4 and 5 for Baumann 32 actuators, figures 10 and 11 for Baumann 54 actuators, and figure 14 for Baumann 70 actuators show the correct assembly configurations for air-to-extend and air-to-retract valves. Notice that both types include the same parts, but they are arranged differently. The following sections detail the disassembly and assembly instructions.

Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any spring precompression.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Field Conversion - ATE to ATR or ATR to ATE

Except for the Baumann 70, these actuators can be changed in the field from air-to-extend (ATE) operation to air-to-retract operation, or from ATR to ATE operation. If you are making this change without changing the bench range, you can reuse the same parts. The parts are simply assembled in a different way. This is described in more detail in the following sections. The following sections list the disassembly and reassembly instructions.

Note

Baumann 70 actuator is available in ATR only.

Field conversion cannot be done on dual-stop actuators.

WARNING

To avoid personal injury or property damage due to actuator springs being under compression, remove the long cap screws last.

The upper actuator casing may remain fixed to the diaphragm and lower casing during disassembly, even if the casing cap screws have been loosened. If this happens, the actuator springs are still under compression. The upper casing could suddenly come loose and jump, due to the compressed energy of the springs. If the upper casing is stuck to the diaphragm and lower casing when you begin loosening the casing cap screws, pry the casings apart with a prying tool. Always be sure that the springs are dispersing energy and the upper casing is moving against the long bolts during disassembly.

WARNING

To avoid personal injury or property damage by uncontrolled movement of the actuator yoke, loosen the body/yoke nuts or bonnet/yoke nuts by following the instructions in the next step. Do not remove a stuck actuator by pulling on it with equipment that can stretch or store energy in any other manner. The sudden release of stored energy can cause uncontrolled movement of the actuator yoke.

Removing the Actuator from the Valve

1. For an air-to-retract (ATR) actuator: Apply 1 bar (15 psi) for Baumann 16 and 32 actuators, or 1.4 bar (20 psi) for Baumann 54 and 70 actuators, to the signal air inlet located in the lower diaphragm case (key 43). This will lift the plug and stem (4/5) away from the valve seat.

For an air-to-extend (ATE) actuator: Disconnect the signal air line connected to the upper diaphragm case (key 43). This will assure that the actuator is vented and that the valve plug and stem (4/5) are fully lifted away from the valve seat.
2. For both types: Place a wrench on the flats of the actuator stem. With an additional wrench, engage the upper locknut (key 27) on the stem and back out the stem about 6.4 mm (1/4 inch). (This procedure will prevent the actuator stem from turning and causing damage to the diaphragm.)
3. Loosen the yoke drive nut (key 9).
4. Using the wrench to work against one of the counter-tightened nuts, turn the valve stem (key 5) completely down until the end unthreads from the actuator stem (key 26).
5. Remove the travel indicator (key 58) from the valve stem (key 5). Loosen the locknuts (key 27) and remove them. Remove the yoke drive nut (key 9).
6. Lift the actuator assembly off of the valve bonnet (key 8).
7. Disconnect airline from ATR actuators.

Disassembling the Actuator

1. Remove the actuator from the valve as described earlier.
2. Remove the cap screws (key 45) and nuts (key 46). Loosen the nuts from the cap screws gradually and evenly. Some units may have a combination of longer and shorter screws. After removing the shorter screws, the remaining longer screws must be loosened evenly. The springs put a lot of force on the diaphragm cases (keys 43 and 44). It is important to release the spring tension gradually before you try to open them.
3. Remove the upper diaphragm case (key 44) and note the position of the parts inside. For the Baumann 70 actuator, the upper diaphragm plate (key 40) must also be removed.
4. Except for the Baumann 16 actuator, lift out the actuator stem (key 26) with the diaphragm plate (key 40) and the diaphragm (key 39). For the Baumann 16 actuator, loosen locknut (key 30) and remove the stem (key 26) through the bottom.
5. For Baumann 32, 54, and 70 actuators, the lower part of the actuator stem (key 26) has flats. Use these flats to clamp the lower end of the stem into a vise. Unscrew the nylon insert locknut (key 30). On an ATE unit, remove the washer (key 112, key 116 for the Baumann 54 actuator), diaphragm (key 39), diaphragm plate (key 40), and for the Baumann 32 actuator, stop cup (key 79). **NOTE: There is not a stop cup for the Baumann 16 actuator. (An ATR unit has the same parts, but they are attached in a different order.)**
6. Replace the diaphragm (key 39) and the O-ring(s) (key 50) if these parts are damaged.

Reassembling the ATE Actuator

1. Use the flats on the actuator stem (key 26) to grip the lower end of the stem in a vise.
2. For the Baumann 32 actuator, place the stop cup (key 79) in position on the upper end of the stem. On an ATE actuator, the stop cup faces down.
3. Place the diaphragm plate (key 40) on the upper end of the stem (key 26), also facing down.
4. Place the diaphragm (key 39) in position. The curved part of the diaphragm should open downward.
5. Place the washer (key 112, key 116 for the Baumann 54 actuator) over the opening in the diaphragm plate.
6. Thread the nylon insert locknut (key 30) onto the end of the stem (key 26) and tighten it.
7. Turn the assembly upside-down, and grip the nylon insert locknut (key 30) in the vise.
8. Place the springs (key 22) onto the diaphragm plate (key 40). Each spring should be centered on one of the raised bosses on the plate.
9. Slide the stop collar (key 115) over the free end of the actuator stem (key 26).
10. Check to see that the O-ring (key 50) is in position on the actuator stem (key 26).
11. Apply some light grease to the O-ring (key 50) and to the surface of the actuator stem (key 26).
12. Slide the lower diaphragm case (key 43), with the actuator yoke (key 17) attached, over the actuator stem (key 26). Make sure that the outer bolt holes of the lower diaphragm case (key 43) line up with the holes in the diaphragm (key 39). If there is interference with any of the springs, rotate the case into another position.
13. Remove the assembly from the vise. Press on the diaphragm assembly slightly to compress the springs. Flip over the assembly and reattach the upper diaphragm case (key 44). As you do this, be sure that all of the springs are upright, and none of them are sitting on the bolt heads. Insert the cap screws (key 45) and tighten the nuts (key 46). It may be necessary to compress the springs slightly to start the nuts. Tighten the nuts evenly, and cross from one side of the assembly to the other as you tighten. This will ensure that the spring tension is taken up evenly.
14. Apply air pressure to the actuator and check for friction or leakage. The actuator should travel smoothly through the entire travel range. Apply leak detection fluid to the area around the guide bushing (key 54). Also check for leaks around the outer edge of the diaphragm (key 39).
15. Make the adjustments described in the section on Bench Range Adjustment - Air-to-Extend (ATE) Valve.

Reassembling the ATR Actuator

1. Use the flats on the actuator stem (key 26) to grip this part in a vise.
2. Place the washer (key 112, key 116 for the Baumann 54 actuator) over the threaded part of the actuator stem (key 26).
3. Place the diaphragm (key 39) in position. The curved part of the diaphragm should open upward.
4. Place the diaphragm plate (key 40) onto the upper end of the stem (key 26), also facing up.
5. For the Baumann 32 actuator, place the stop cup (key 79) in position on the upper end of the stem (key 26). On an ATR actuator, the stop cup faces up.
6. Thread the nylon insert locknut (key 30) onto the end of the stem (key 26) and tighten it.
7. Slide the stop collar (key 115) over the free end of the actuator stem (key 26).
8. Check to see that the O-ring (key 50) is in position on the actuator stem (key 26).
9. Apply some light grease to the O-ring (key 50), and to the surface of the actuator stem (key 26).
10. Slide the actuator stem into the lower diaphragm case (key 43). Turn the assembly so the holes in the diaphragm (key 39) line up with the holes in the diaphragm case (key 43).
11. Place the springs (key 22) onto the diaphragm plate (key 40). Each spring should be centered on one of the raised bosses on the plate.
12. Reattach the upper diaphragm case (key 44). As you do this, be sure that each of the springs is upright. Insert the cap screws (key 45) and tighten the nuts (key 46). It may be necessary to press down on the upper diaphragm case (key 44) slightly to compress the springs slightly and start the nuts. Tighten the nuts evenly, and cross from one side of the assembly to the other as you tighten. This will ensure that the spring tension is taken up evenly.
13. Apply air pressure to the actuator and check for friction or leakage. The actuator should travel smoothly through the entire travel range. Apply leak detection fluid to the area around the guide bushing (key 54). Also check for leaks around the outer edge of the diaphragm.
14. Make the adjustments described in the section on Bench Range Adjustment-Air-to-Retract (ATR) Valve.

WARNING

To avoid personal injury or equipment damage due to possible sudden shifting or falling of the valve assembly, do not lift the valve assembly by the handwheel.

Actuator Maintenance

A routine maintenance schedule might call for regular replacement of the O-ring(s) (key 50) or the diaphragm (key 39). Follow the disassembly and reassembly instructions listed earlier.

Handwheel Operation

For air-to-retract actuators, turn handwheel clockwise to manually retract the stem and counterclockwise to extend the stem. The small locking knob on top of the handwheel assembly enables the user to lock the desired handwheel position.

For an air-to-extend actuator, turn the handwheel clockwise to manually extend the stem and counterclockwise to retract the stem. The lever on the handwheel stem enables the user to lock the desired handwheel position.

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number, part name, and desired material using the Parts List table.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and actuator, and could cause personal injury and property damage.

Neither Emerson, nor any of its affiliated entities assume responsibility for the selection, use or maintenance of any product. Responsibility for proper selection, use, and maintenance of any product remains solely with the purchaser and end user.

Baumann and Fisher are marks owned by one of the companies in the Emerson business unit of Emerson Electric Co. Emerson and the Emerson logo are trademarks and service marks of Emerson Electric Co. All other marks are the property of their respective owners.

The contents of this publication are presented for informational purposes only, and while every effort has been made to ensure their accuracy, they are not to be construed as warranties or guarantees, express or implied, regarding the products or services described herein or their use or applicability. All sales are governed by our terms and conditions, which are available upon request. We reserve the right to modify or improve the designs or specifications of such products at any time without notice.

Section 1: Introduction

Baumann SV electric actuators (Figure 1) provide high accuracy for industrial temperature, HVAC and sanitary applications.

This system is specifically designed for Fisher Baumann sliding stem-control valves.

1.1 Scope of the Manual

This instruction manual includes installation, maintenance and parts information for Baumann SV electric actuators.

WARNING

Do not install, operate or maintain Baumann SV electric actuators without fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

1.2 Actuator Specifications

Table 1. Actuator Specifications

ACTUATOR TYPE		SVX24-MFT	SVK24-MFT
POWER FAILURE		Lock in last position	Fail Open/Fail Closed
ACTION		Direct or Reverse	
POWER CONSUMPTION		4 W	8.5 W
TRANSFORMER SIZE		6 VA (class 2 power source)	21 VA (class 2 power source)
TRAVEL		12.7 and 19.1 mm / 0.50 and 0.75 in.	
MATERIAL	Housing	Aluminum die cast and plastic casing	
	Yoke Legs	Aluminum	
ENCLOSURE RATING		NEMA 2, / IP 54 UL Enclosure Type 2	
INPUT SIGNAL		2 to 10 V DC or 4 to 20 mA input signal	
POWER SUPPLY		24 V AC or 24 V DC	
ELECTRICAL CONNECTION		3 ft, 18GA appliance cable, 0.5 in. conduit fitting	
AMBIENT TEMPERATURE		-30 to +50°C / -22 to +122°F	
RELATIVE HUMIDITY RANGE		5 to 95% RH, non-condensing	
OUTPUT THRUST		1500 N / 337 lbf	
VALVE STEM POSITION FEEDBACK OUTPUT		2 to 10 V DC / 0.5 mA maximum	
SHUTOFF CLASS		Class IV or VI per ANSI/FCI 70-2 (Refer to Valve Technical Bulletin)	
TRAVEL TIME		35 seconds	
NOISE LEVEL		< 45 dB(A)	
MANUAL OVERRIDE		4 mm Hex Head	
POSITION INDICATION		Travel Indicator on Yoke	
SPLIT RANGE CAPABILITY		Yes	
AGENCY APPROVALS		CE (A), UL 60730-1A/-2 -14, CSA E60730-1:02 (CE approval for actuator only)	
WEIGHT		1.3 kg / 2.9 lbs	1.6 kg / 3.6 lbs

Email: education@emerson.com

emerson.com/en/final-control/services/valve-training

Section 2: Installation

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

WARNING

When ordered, this actuator configuration was selected for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the actuator could result in parts damage, malfunction of the actuator or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended without first contacting your [Emerson sales office](#).

WARNING

Keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem.

Select wiring and/or cable glands that are rated for the environment of use (such as hazardous area, ingress protection and temperature). Failure to use properly rated wiring and/or cable glands can result in personal injury or property damage from fire or explosion.

Wiring connections must be in accordance with local, regional and national codes for any given hazardous area approval. Failure to follow the local, regional and national codes could result in personal injury or property damage from fire or explosion.

2.1 Recommended Installation Location

It is permissible to install the SV actuator upright or horizontally. Allow 12 in. of clearance for removal of the actuator.

NOTICE

To avoid equipment damage, do not install the valve with the stem in a downward position. Equipment damage may occur from liquids leaking into the actuator cover.

NOTE

Assembly can be mounted horizontally or vertically. Do not install with the actuator below the pipe.

Figure 2. Actuator Parts

Table 2. Actuator Assembly Parts List

KEY NO.	DESCRIPTION	QTY
17	Actuator yoke	1
25	Stem connector	1
26	Stem adapter	1
44	SV actuator	1
56	Travel scale	1
58	Travel indicator	1
59	Spacer	1

Table 3. Common Valve Parts for Fisher Baumann 24000, 24000C, 24000S, 24000F, 24000SVF and 24000CVF

KEY NO.	DESCRIPTION
1	Valve body
2	Seat ring
4	Plug
5	Stem
8	Bonnet
9	Drive nut
10	Packing follower
27	Locknuts

See Table 2 for actuator parts/key numbers referenced in this Installation section.
See Table 3 and also refer to the appropriate Fisher Baumann valve instruction manual for valve parts referenced in this Installation section.

1. Before starting, ensure you have the correct actuator part number for the necessary stroke and locate the following parts: stem locknuts, travel indicator, bonnet, yoke drive nut, plug and stem assembly, packing follower. Refer to the assembly instructions for the appropriate Fisher Baumann control valve for parts identification.
2. Place the body of the valve in a vise. Clamp the flat end faces of the valve.
3. Connect the actuator wires in the proper setup. The black and red wires should be connected to power and the black and white wires should be connected to the input signal. Cycle the actuator to the upper travel point.
4. When mounting the actuator assembly to the valve body, the hole in the yoke plate should fit over the top of the valve stem. Tilt the top of the actuator back at an angle so you can access the top of the valve stem.
5. Position the yoke drive nut over the valve stem with the flat side facing up (the rounded side should face down, toward the top surface of the yoke plate).
6. Thread two locknuts onto the valve stem. Finger-tighten both nuts down as far as possible. Lock the nuts together using two wrenches to counter-tighten them. By turning the locked nuts with a wrench, you will be able to turn the valve stem in step 8 without damaging the surface of the valve stem.

NOTICE

When assembling or disassembling the valve, do not turn the valve stem while the plug is touching the valve seat. This will damage the valve's seating surfaces.

7. Apply anti-seize compound to the first few threads of the valve stem. Lift the valve stem up so that the plug is off the seat. Turn the valve stem so that the threads begin to catch in the lower end of the stem adapter (key 26). Using one wrench placed on the lower counter-tightened nut and one wrench on the stem adapter (key 26), turn the valve stem up until you feel resistance, then back off or unscrew the stem adapter one full turn. Be sure that the actuator yoke plate is firmly seated on the bonnet.
8. Using a hammer and punch, tighten the drive nut.
9. Place the spacer (key 59) on top of the stem adapter (key 26). Place the travel indicator disk on top of the spacer and tighten the stem connector (key 25) to the stem adapter (key 26) until rigid.
10. Check the seat leak and adjust the stem adapter down as required to achieve shutoff.
11. Using two wrenches, unlock the two counter-tightened locknuts. Holding the stem adapter (key 26) with a wrench, turn the locknuts, one at a time, up until they are locked together against the stem adapter (key 26).
12. With the valve in the closed position, add the travel indicator sticker (key 56). The closed line on the travel indicator sticker (key 56) should be aligned with the travel indicator (key 58) at this point.

2.2 Additional Calibration and Setup

For additional calibration and setup information, please visit [71821-0001.B](#), Quick Mount Visual Instruction Manual for UFVL Linkage with LV and SV Series Actuators. The calibration PC tool, as well as MFT documentation, is available.

2.3 SV Manual Override

Figure 3. SV Manual Override

Y2A7087

Section 3: Maintenance

WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.
- Do not tamper with actuator positioning bolts located on the adjustable yoke legs.

NOTE

It is recommended that you review Figure 2 before performing maintenance or installation of the SV electric actuator.

Section 4: Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always mention the valve serial number. When ordering replacement parts, also specify the key number and part name shown in Table 2.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and could cause personal injury and property damage.

X1430

Introduction

Scope of Manual

This instruction manual includes installation, maintenance and parts information for NPS 2 through 4 CCV-N fuel gas control valves. These valves are used in gas turbines which meter the fuel gas to the combustion chamber of the turbine and provide linear flow with the ability to choke very quickly at a low pressure drop. Refer to separate manuals for instructions covering the actuator and accessories.

Do not install, operate, or maintain CCV-N valves without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Table 1. Specifications

<

1. The pressure/temperature limits in this manual and any applicable standard or code limitation for valve should not be exceeded.

Description

CCV-N valves are single port, angle-style, and balanced or unbalanced valves with metal seat, seat ring retainer guide, and push-down-to-close valve plug action.

Educational Services

emerson.com/fishervalvetraining

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Personal injury or equipment damage caused by sudden release of pressure may result if the valve assembly is installed where service conditions could exceed the limits given in table 1 or on the appropriate nameplates. To avoid such injury or damage, provide a relief valve for over-pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

When ordered, the valve configuration and construction materials were selected to meet particular pressure, temperature, pressure drop, and controlled fluid conditions. Since some valve body/trim material combinations are limited in their pressure drop and temperature ranges, do not apply any other conditions to the valve without first contacting your [Emerson sales office](#).

1. Before installing the valve, inspect the valve and associated equipment for any damage and any foreign material.
2. Make certain the valve body interior is clean, that pipelines are free of foreign material, and that the valve is oriented so that pipeline flow is in the same direction as the arrow on the side of the valve.
3. It is recommended the valve should be installed in the vertical orientation with the actuator vertical above the valve. Other positions may result in uneven valve plug, seal set, seat ring, seat ring retainer, packing wear and improper operation. For more information, consult your Emerson sales office.
4. It is recommended the valve upstream pipe inside diameter should match or be close to valve body inlet inside diameter to reduce valve inlet turbulence.
5. It is recommended to have a length of 6 to 12 pipe diameters of straight pipe upstream of the valve body inlet and 4 to 8 pipe diameters length downstream of the valve seat ring outlet. The straight pipe upstream and downstream of the valve body should have a smooth inside surface with no weld slag or other inside surface irregularities. It is recommended that pipe reducers not be installed in the straight pipe upstream and downstream of the valve.
6. Use a suitable gasket between valve and pipeline flanges.
7. If continuous operation is required during inspection or maintenance, install a three-valve bypass around the control valve assembly.
8. Refer to the actuator mounting procedure in the appropriate actuator instruction manual.

⚠ WARNING

Personal injury could result from packing leakage. Valve packing was tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

Valves with ENVIRO-SEAL live-loaded packing or HIGH-SEAL live-loaded packing will not require this initial re-adjustment. See the Fisher instruction manuals, ENVIRO-SEAL Packing System for Sliding-Stem Valves ([D101642X012](#)) or HIGH-SEAL Live-Loaded Packing System ([D101453X012](#)) (as appropriate), for packing instructions. If you wish to convert your present packing arrangement to ENVIRO-SEAL packing, refer to the retrofit kits listed in the Parts Kit sub-section near the end of this manual.

Maintenance

Valve parts are subject to normal wear and must be inspected and replaced as necessary. Inspection and maintenance frequency depends on the severity of service conditions. This section includes instructions for packing maintenance and trim maintenance. All maintenance operations may be performed with the valve in the line.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Release the actuator loading pressure and relieve any actuator spring pre-compression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

CAUTION

Follow instructions carefully to avoid damaging the product surfaces, which could result in damage to the product. Protect all surfaces of the valve plug, valve seat ring, and seat ring retainer during maintenance to ensure control valve accuracy and choking performance is not affected.

Note

Whenever a gasket seal is disturbed by removing or shifting parts, a new gasket should be installed upon reassembly. This is necessary to ensure a good gasket seal, since the used gasket may not seal properly.

Packing Maintenance

Note

For valves with ENVIRO-SEAL packing, see the Fisher instruction manual, ENVIRO-SEAL Packing System for Sliding-Stem Valves, [D101642X012](#), for packing instructions.

If there is undesirable packing leakage, first try to limit the leakage and establish a stem seal by tightening the packing flange nuts.

If the packing is relatively new and tight on the stem, and if tightening the packing flange nuts does not stop the leakage, it is possible that the valve stem is worn or nicked so that a seal cannot be made. The surface finish of a new valve stem is critical for a good packing seal. If the leakage comes from the outside diameter of the packing, it is possible that the leakage is caused by nicks or scratches around the packing box wall. If performing any of the following procedures, inspect the valve stem and packing box wall for nicks and scratches.

Replace Packing

WARNING

Refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, and releases all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment. Observe the **Warnings** at the start of the Maintenance section.
2. Disconnect the operating lines from the actuator and any leak-off piping from the bonnet. Disconnect the stem connector and remove the actuator from the valve.
3. Loosen the packing flange nuts (key 5, figures 3, 4, and key 212, figure 5) so that the packing is not tight on the valve stem (key 7, figures 6, 7, 8, 12, 13, and 14). Remove any travel indicator parts and stem locknuts from the valve stem threads.

WARNING

To avoid personal injury or property damage caused by uncontrolled movement of the bonnet, loosen the bonnet by following the instructions in the next step. Do not remove a stuck bonnet by pulling on it with equipment that can stretch or store energy in any other manner. The sudden release of stored energy can cause uncontrolled movement of the bonnet.

Figure 2. Packing Arrangements

DOUBLE PTFE

NOTE:

1 PAKING SET (KEY 6) CONTAINS A FEMALE ADAPTER, V-RING PACKING RINGS, MALE ADAPTER, AND LOWER WIPER RINGS.

GRAPHITE LEAK-OFF

NOTE: INSTALL SACRIFICIAL WASHERS AT PLACES MARKED "W"

1 HAS THE APPEARANCE OF DIE FORMED GRAFOIL MATERIAL.
2 HAS THE APPEARANCE OF A WOVEN OR BRAIDED RING.

4. Hex nuts (key 16, figures 6, 7, 8, 12, 13, and 14) attach the bonnet (key 1, figures 3, 4, and 5) to the body (key 1, figures 6, 7, 8, 12, 13, and 14). Loosen these nuts approximately 3 mm (1/8 inch). Then loosen the body-to-bonnet gasketed joint by either rocking the bonnet or prying between the bonnet and valve. Work the prying tool around the bonnet until the bonnet loosens. If no fluid leaks from the joint, remove the nuts or cap screws completely and carefully lift the bonnet off the valve.

CAUTION

Avoid damaging the seating surface caused by the valve plug and stem assembly dropping from the bonnet (key 1, figure 3) after being lifted partway out. When lifting the bonnet, temporarily install a valve stem locknut on the valve stem. The locknut will prevent the valve plug and stem assembly from dropping out of the bonnet.

5. Remove the locknut and separate the valve plug and stem from the bonnet. Set the parts on a protective surface to prevent damage to gasket or seating surfaces.
6. Remove the bonnet gasket (key 10 and 12, figures 6, 7, 8, 12, 13, and 14) and cover the opening in the valve to protect the gasket surface and prevent foreign material from getting into the valve body cavity.

CAUTION

To prevent possible product damage, cover the opening in the valve in the following procedure to prevent foreign material from getting into the valve body cavity.

7. Remove the packing flange nuts, packing flange, upper wiper, and packing follower when applicable (keys 3, 5, and 13, figure 4). For Enviro-Seal Graphite ULF packing, remove the packing flange nuts, packing flange, and spring pack

assembly (keys 201, 212, and 217, figure 5). Carefully push out all the remaining packing parts from the valve side of the bonnet using a rounded rod or other tool that will not scratch the packing box wall. Clean the packing box and the metal packing parts.

8. Inspect the valve stem threads and packing box surfaces for any sharp edges which might cut the packing. Scratches or burrs could cause packing box leakage or damage to the new packing. If the surface condition cannot be improved by light sanding, replace the damaged parts by following the appropriate steps in the Trim Maintenance procedure.
9. Remove the covering protecting the valve body cavity and install new bonnet gaskets (key 10 and 12, figures 6, 7, 8, 12, 13, and 14) making sure the gasket seating surfaces are clean and smooth. Then slide the bonnet over the stem and onto the stud bolts (key 15, figures 6, 7, 8, 12, 13, and 14.)

⚠ WARNING

Personal injury or damage to equipment could occur if improper stud and nut materials or parts are used. Do not operate or assemble this product with stud(s) and nut(s) that are not approved by Emerson/Fisher engineering and/or listed on the serial card provided with this product. Use of unapproved materials and parts could lead to stresses exceeding the design or code limits intended for this particular service. Install studs with the material grade and manufacturer's identification mark visible. Contact your [Emerson sales office](#) representative immediately if a discrepancy between actual parts and approved parts is suspected.

10. Lubricate the bonnet studs (key 15, figure 6, 7, or 8) and all surfaces the studs and nuts come into contact with. Make sure the nuts material matches the valve specification and set the nut surface with material specification stamp facing up, therefore it is visible. Tighten the nuts (key 16, figures 6, 7, 8, 12, 13, and 14) in a uniform, multistage cross pattern. Monitor the distance between the bonnet and body and keep it even to ensure that the bonnet is being torqued evenly. Use no more than 1/4 of the specified torque as indicated in table 2. Repeat the crisscross pattern, work up to the specified torque in 1/4 increments until the final torque is achieved. Wait a minimum of 2 minutes to allow for gasket/screw relaxation and recheck the torque, retightening as necessary. After final torquing, ensure there is an even gap and that the metal-to-metal contact between the valve body (or bonnet spacer) and bonnet is achieved around the entire circumference of the body-bonnet joint.

Table 2. Body-to-Bonnet Torque Guidelines

VALVE SIZE, NPS	BOLT TORQUES			
	SA193-B7 Studs		S20910 (Nitronic 50) Studs	
	N•m	Lbf-in	N•m	Lbf-in
2	91	67	60	44
3	122	90	85	63
4	163	120	118	87

11. Install new packing and the metal packing box parts according to the appropriate arrangement in figure 2. For Enviro-Seal Graphite ULF packing only, see figure 5, parts list in this instruction manual and ENVIRO-SEAL Packing System for Sliding-Stem Valves Instruction Manual ([D101642X012](#)) for packing arrangement and installation, complete step 11, then move to step 14. Place a smooth-edged pipe over the valve stem and gently tap each soft packing part into the packing box.
For all other packing, except Enviro-Seal packing, move to step 12.
12. Slide the packing follower, upper wiper (not applicable for graphite leak-off packing), and packing flange (keys 3,13, 12, figure 3 or 4) into position. Lubricate the packing flange studs (key 4, figure 3 or 4) and the faces of the packing flange nuts (key 5, figure 3 or 4). Install the packing flange nuts.
13. For **graphite leak-off packing**, tighten the packing flange nuts to the maximum recommended torque shown in table 3. Then, loosen the packing flange nuts, and retighten them to the recommended minimum torque shown in table 3.
For **other packing types**, tighten the packing flange of the nuts alternatively in small increments until one of the nuts reaches the minimum recommended torque shown in table 3. Then, tighten the remaining flange nut until the packing flange is level and at a 90-degree angle to the valve stem.

Table 3. Recommended Torque for Packing Flange Nuts

Packing	STEM SIZE		Rating	MINIMUM TORQUE		MAXIMUM TORQUE	
	mm	inch		N•m	Lbf-in	N•m	Lbf-in
PTFE Packing	12.7	1/2	CL300	3	30	5	42
Graphite Leak-off Packing	12.7	1/2	CL300	7	59	10	88
			CL600	9	81	14	122

14. Mount the actuator on the valve assembly and reconnect the actuator and valve stem according to the procedure in the appropriate actuator instruction manual.

Trim Maintenance

Non-Bore Seal Trim Constructions

⚠ WARNING

Refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

CAUTION

Follow instructions carefully to avoid damaging the product surfaces, which could result in damage to the product. Protect all surfaces of the valve plug, valve seat ring, and seat ring retainer during maintenance to ensure control valve accuracy and choking performance is not affected.

Disassembly

1. Remove the actuator and the bonnet according to steps 1 through 6 of the Replacing Packing procedure in the Maintenance section.

⚠ WARNING

To avoid personal injury due to leaking fluid, avoid damaging gasket sealing surfaces. The surface finish of the valve stem (key 7, figure 6, 7, 8, 12, and 13) is critical for making a good packing seal. The inside surface of the seat ring retainer (key 3, figure 6, 7, 8, 12, and 13), is critical for smooth operation of the valve plug. The seating surfaces of the valve plug (key 2, figure 6, 7, 8, 12, and 13) and seat ring (key 9, figure 6, 7, 8, 12, and 13) are critical for proper shutoff. Unless inspection reveals otherwise, assume all these parts are in good condition and protect them accordingly.

2. Remove the packing flange nuts, packing flange, upper wiper (not applicable for graphite leak-off packing), and packing follower (keys 3, 5, 12, and 13, figure 3 or 4). For Enviro-Seal packing, remove the packing flange nuts, packing flange, and spring pack assembly (key 201, 212, and 217, figure 5.) Carefully push out all the remaining packing parts from the valve side of the bonnet using a rounded rod or other tool that will not scratch the packing box wall. Clean the packing box and the metal packing parts.
3. Inspect the valve stem threads and packing box surfaces for any sharp edges which might cut the packing. Scratches or burrs could cause packing box leakage or damage to the new packing. If the surface condition cannot be improved by light sanding, replace the damaged parts.
4. On a CCV-N design with bonnet spacer, remove the bonnet spacer (key 32, figure 6 and 12) and associated gaskets (key 10 and 12, figure 6 and 12) on top of the spacer without rotating the seat ring retainer (key 3, figure 6 and 12).

5. Mark the orientation between valve body (key 1, figures 6, 7, 8, 12, and 13) and seat ring retainer (key 3, figure figures 6, 7, 8, 12, and 13). Remove the seat ring retainer, valve plug and stem assembly, and associated gaskets (key 10, 12, figures 6, 7, 8, 12, and 13).
6. Separate the plug stem assembly and seat ring retainer (key 3, figures 6, 7, 8, 12, and 13) by sliding the plug stem assembly through the bottom of seat ring retainer.
7. Remove the seat ring (key 9, figure figures 6, 7, 8, 12, and 13) and seat ring gasket (key 13, figures 6, 7, 8, 12, and 13).
8. For all constructions, inspect parts for wear or damage which would prevent proper operation of the valve. Replace or repair trim parts according to the following procedure for plug maintenance procedure.

NPS 4 Balanced Bore-Seal Trim Maintenance

⚠ WARNING

Refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

1. Remove the actuator and the bonnet according to steps 1 through 6 of the Replacing Packing procedure in the Maintenance section.

⚠ WARNING

To avoid personal injury due to leaking fluid, avoid damaging gasket sealing surfaces. The surface finish of the valve stem (key 7, figure 14) is critical for making a good packing seal. The inside surface of the seat ring retainer (key 3, figure 14) is critical for smooth operation of the valve plug. The seating surfaces of the valve plug (key 2, figure 14) and seat ring (key 9, figure 14) are critical for proper shutoff. Unless inspection reveals otherwise, assume all these parts are in good condition and protect them accordingly.

2. Remove the packing flange nuts, packing flange, and packing follower (keys 3, 5, and 13, figure 4). For Enviro-Seal packing, remove the packing flange nuts, packing flange and spring pack assembly (key 201, 212 and 217, figure 5). Carefully push out all the remaining packing parts from the valve side of the bonnet using a rounded rod or other tool that will not scratch the packing box wall. Clean the packing box and the metal packing parts.
3. Inspect the valve stem threads and packing box surfaces for any sharp edges which might cut the packing. Scratches or burrs could cause packing box leakage or damage to the new packing. If the surface condition cannot be improved by light sanding, replace the damaged parts.
4. On a CCV-N design with bonnet spacer, remove the bonnet spacer (key 32, figure 14) and associated gaskets (key 10 and 12, figure 14) without rotating the seat ring retainer (key 3, figure 14).
5. Mark the orientation between valve body (key 1, figure 14), and seat ring retainer (key 3, figure 14).
6. Gently pull the valve stem (key 7, figure 14) up to lift the whole valve plug and stem assembly, seat ring retainer, Bore-seal and piston rings set (key 2, 4, 7, 8, 17, 18, figure 14) out of valve body (key 1 in figure 14). The plug stem assembly contains sensitive guiding and sealing surfaces on its outside diameter and care must be taken in its handling.
7. Locate the break between sections of the piston rings (key 18, figure 14), which should be out of seat ring retainer by holding the valve stem and seat ring retainer. Using an appropriate tool such as a flat-blade screwdriver, carefully pry out the piston rings from the grooves in the Bore Seal retainer.
8. By holding both valve stem and seat ring retainer, place the whole valve plug and stem assembly, seat ring retainer, Bore-seal trim set on a soft surface such as clean cloth, which will not damage the trim. The valve plug and stem assembly, seat ring retainer and Bore-seal will remain as a whole trim set. Do not rotate the valve plug and stem assembly within seat ring retainer. Do not apply any axial force into valve stem which might damage the Bore-seal.

9. Remove the seat ring (key 9, figure 14) and seat ring gasket (key 13, figure 14).
10. Inspect parts for wear or damage which would prevent proper operation of the valve. Replace or repair trim parts according to the following procedure for NPS 4 Bore-seal plug maintenance procedure.

Valve Plug Maintenance (Except NPS 4 Balanced Bore-seal Plug)

Except where indicated, NPS 2 key numbers are referenced in figure 6 or 12, NPS 3 key numbers are referenced in figure 7 or 13, and NPS 4 key numbers are referenced in figure 8.

Note

Due to the design requirement of this product, the valve and stem are precision-matched and the stem is not replaceable. If damaged, the valve plug and stem must be replaced as an assembly. Contact your [Emerson sales office](#) for parts replacement.

CAUTION

To avoid the valve plug seal ring (key 24) not sealing properly, be careful not to scratch the surfaces of the ring groove in the valve plug or any of the surfaces of the replacement ring.

Do not remove the valve stem from the plug/retainer assembly unless you are planning to replace the valve stem. Never reuse an old valve stem with a new plug or reinstall a valve stem after it has been removed. Replacing a valve stem requires drilling a new pin hole in the stem. This drilling weakens the stem and damage may result in service.

1. With the valve plug (key 2) removed according to the Disassembly portion of the Trim Maintenance procedure, proceed as appropriate:
2. **NPS 2 design for application up to and including 316°C (600°F) (figure 6):** Mark the orientation between valve plug (key 2) and seal retainer (key 4). Punch out the pin (key 8) that connects the valve plug (key 2), stem (key 7) and seal retainer (key 4). Remove the seal retainer (key 4) with a spanner wrench or strap wrench while counter-holding the valve plug (key 2) with a second strap wrench, or other suitable tool, to prevent rotation of the valve plug on the valve stem (key 7). Slide the upper anti-extrusion ring, seal ring, bi-directional back up ring, seal ring, and anti-extrusion ring (key 63, 24, and 33) off the plug.

Inspect all parts for defects and cleanliness and replace the damaged parts. The removed seal set soft parts should not be reused. To install the new seal parts, slide the lower anti-extrusion ring, seal ring, bi-directional back up ring, seal ring, and upper anti-extrusion ring (key 63, 24, and 33) into the plug, as shown in figure 6. Apply anti-seize lubricant (key 45) to the thread of the seal retainer and flat mating surfaces between the seal retainer and plug (key 2 and 4). Then, install the seal retainer (key 4) into the plug (key 2) and tighten it with a spanner wrench or strap wrench until the pin holes and previous mark are aligned. Once the holes are aligned, secure the seal retainer (key 4) to the plug stem assembly with a new pin (key 8). Make sure the pin is inserted completely into the assembly with 0.025" depth from the radial surface.

CAUTION

To avoid damaging the seal ring, slowly and gently stretch it for the following procedure. Avoid jerking sharply on the ring.

NPS 3 design for application up to and including 316°C (600°F) (figure 7): Remove the retainer ring (key 26) off the groove, and slide the back up ring, upper anti-extrusion ring, seal ring, bidirectional back up ring, seal ring, and anti-extrusion ring (key 63, 24, 25, and 33) off the plug.

Inspect all parts for defects and cleanliness and replace the damaged parts. The removed seal set soft parts should not be reused. To install the new seal parts, slide the lower anti-extrusion ring, seal ring, bi-directional back up ring,

seal ring, upper anti-extrusion ring, and back up ring (key 63, 24, 25, and 33) into the plug, as shown in figure 7, view B. Then install the retaining ring (key 26) by inserting one end in the groove and pressing the ring into the groove while turning the plug. Again, be careful not to scratch any surfaces of the ring or plug.

NPS 4 design for application up to and including 316°C (600°F) (figure 8): Using a punch, drive the pin (key 5) further into the pin hole, as shown in figure 9. To prevent damaging the outer diameter of the plug, use a face spanner wrench to unthread the seal retainer (key 4) from the plug (key 2) using the pin holes on the top surface of the seal retainer, as shown in figure 9. Once the seal retainer is unthreaded, slide the upper anti-extrusion ring, seal ring, bi-directional back up ring, seal ring, and anti-extrusion ring (key 63, 24, and 33) off the plug.

Inspect all parts for defects and cleanliness and replace the damaged parts. The removed seal set soft parts should not be reused. To install the new seal parts, slide the lower anti-extrusion ring, seal ring, bi-directional back up ring, seal ring, and upper anti-extrusion ring (key 63, 24, and 33) into the plug, as shown in figure 8, view B. Then, apply anti-seize lubricant (key 45) to the seal retainer threads and flat mating surfaces between the seal retainer and plug (key 2 and 4). Install the seal retainer into the plug (key 2 and 4) and tighten it with a spanner wrench until the pin holes are aligned. Retain the seal retainer (key 4) to the plug (key 2) by pinning a new pin (key 5) into one of the remaining pin holes with 0.025" depth from the surface. Do not insert the pin into a pin hole that was previously pinned, as shown in figure 9.

NPS 2 and 3 unbalanced design for application above 316°C (600°F) (figure 12 and 13): No seal is required for the unbalanced design. Inspect all parts for defects and cleanliness and replace the damaged parts.

NPS 4 Balanced Bore-seal Valve Plug Maintenance

Except where indicated, NPS 4 Balanced Bore-seal Valve Plug key numbers are referenced in figure 14. Contact your Emerson sales office for Bore Seal trim replacement.

Note

Due to the design requirement of this product, the valve and stem are precision-matched and the stem is not replaceable. If damaged, the valve plug and stem must be replaced as an assembly. The set of valve plug and stem assembly, seat ring retainer and Bore-seal is designed as a whole assembly trim set, which might need special tool and fixture to remove and install. Contact your [Emerson sales office](#) for parts replacement.

CAUTION

To avoid leakage when the valve is returned to service, use appropriate methods and materials to protect all sealing surfaces of the trim parts during maintenance. Use caution when removing piston ring(s) and the Bore Seal plug seal to avoid scratching any sealing surface.

Do not remove the valve stem from the plug/retainer assembly unless you are planning to replace the valve stem. Never reuse an old valve stem with a new plug or reinstall a valve stem after it has been removed. Replacing a valve stem requires drilling a new pin hole in the stem. This drilling weakens the stem and may cause failure in service.

Follow instructions carefully to avoid damaging the product surfaces, which could result in damage to the product. Protect all surfaces of the valve plug, valve seat ring, and seat ring retainer during maintenance to ensure control valve accuracy and choking performance is not affected.

1. With the whole valve plug and stem assembly, seat ring retainer and Bore-seal set (key 2, 4, 7, 8, 17) removed from valve body (key 1), pull the valve stem (key 7) to the top end of seat ring retainer (key 3) as shown in figure 15. Remove the two graphite piston rings (key 18, figure 14). To remove plug retainer for maintenance purpose, locate the staked thread on top of the valve plug (key 2) between the valve plug and plug retainer. The staked thread secures the retainer. Use a drill with a 1/8 inch bit to drill out the staked area of the thread. Drill approximately 1/8

inch into the metal to remove the staking. The seat ring retainer and valve plug should be protected during processing.

2. Loosen the plug retainer (key 4) with strap wrench or spanner wrench and remove plug retainer from the valve plug (key 2). Pull the plug retainer out of valve stem (key 7).
3. Remove the Bore-seal (key 17) without damaging the Bore-seal sealing surface and plug sealing surface.
4. Gently slide or push the plug and stem assembly (key 2, 7) into seat ring retainer (key 3) to move out from the seat ring retainer bottom end.
5. Inspect plug sealing surface. Replace valve plug and stem assembly, and seat ring retainer if wear or damage is found on the sealing, guiding and seat ring retainer window surfaces. Clean all parts if necessary to remove any buildup especially on the sealing, guiding and seat ring retainer window surfaces.
6. Gently slide the plug and stem assembly (key 7) back into seat ring retainer (key 3) from the seat ring retainer bottom end. Hold the seat ring retainer (key 3) and pull the valve stem (key 7) all the way up until there is metal to metal contact between valve plug and seat ring retainer. The two piston ring grooves on top of the plug retainer should stick out of the top of seat ring retainer. Coat new Bore-seal sealing surface and valve plug bore-seal groove sealing surface with high temperature grease. Place the new Bore-Seal plug seal over the top of the valve plug by hand. The Bore-seal opening should be oriented down into the valve plug as shown in view B on figure 14. Do not use uneven force to push the Bore-seal into the valve plug groove.
7. Coat thread of plug retainer (key 4) or valve plug (key 2) with anti-seize lubricant. Hand tighten the plug retainer into valve plug, which might push the Bore-seal into plug sealing groove. Use strap wrench to overcome extra thread friction to tighten plug retainer into valve plug until metal-to-metal contact between them. The Bore-seal will be pushed into the plug Bore-seal groove. To avoid leakage when the valve is returned to service, use appropriate methods and materials to protect all sealing surfaces of the trim parts during maintenance.
8. Pull the valve plug and stem assembly all the way to the top end of the seat ring retainer (key 3) and hold the valve plug and stem assembly so that the plug retainer (key 4) and bore seal are above the top of the seat ring retainer (as shown in Figure 15). Make sure the plug retainer is fully tightened onto the valve plug to ensure a metal-to-metal contact with the valve plug. Stake the thread between the valve plug and plug retainer in one place to deform the thread to secure the plug retainer to the valve plug.
9. The replacement piston rings will arrive in one piece. Use a vise with smooth or taped jaws to break this replacement piston rings into halves. Coat new piston ring surface and plug retainer grooves sealing surface with high temperature grease. Place piston rings into plug retainer therefore the openings of one piston ring would be 90° away from the other piston ring.
10. Gently slide the valve plug, plug retainer, stem, Bore-seal and piston rings assembly into seat ring retainer. Do not try to push the valve plug, plug retainer, stem, Bore-seal and piston rings assembly into seat ring retainer Bore-seal sealing surface, which might require extra actuator force. Do not rotate the valve stem end when the whole assembly is inside seat ring retainer. Set the whole trim set of valve plug, plug retainer, stem, seat ring retainer, Bore-seal and piston rings on a soft surface such as clean cloth, without any movement.

Assembly

Except where indicated, key numbers are referenced in figure 6, 7, 8, 12, 13, and 14.

1. Inspect all parts for damage and cleanliness; remove any burrs on metal valve components.
2. Place a gasket (key 13) into the valve body (key 1) where the seat ring flange seats. Then, insert the seat ring (key 9) into the valve body (key 1). The seat ring (key 9) end will protrude out from the valve body (key 1).
3. Assemble the plug stem assembly of each size into the valve body (key 1) as the following:
4. Inspect the sealing surface of the plug, stem, and seal assembly for nicks and scratches. Then, apply high temperature grease (key 46) sparingly around the spring-loaded seal ring (key 24) or piston rings. For unbalanced design, there is no seal in the valve plug (key 2). Apply high temperature grease (key 46) sparingly around the unbalanced plug guiding surface only.

No lubricant (key 46) should be applied on the balanced or unbalanced plug surfaces which would contact the flow fluid.

5. For NPS 2 and 3 balanced design, carefully insert the bottom end of plug stem seal assembly into the top of the seat ring retainer (key 3) through the inner bore as shown in figure 10. Make sure there is no damage done to the seals. Slide the plug stem seal assembly into the seat ring retainer (key 3) until the top of the plug stem seal assembly is even with the top of the seat ring retainer (key 3). At this point, the plug (key 2) should have a snug fit with the seal ring retainer (key 3).

For NPS 2 and 3 unbalanced design, carefully insert the bottom end of plug stem assembly into the top of the seat ring retainer (key 3) through the inner bore. Make sure there is no damage done to the seals. Slide the plug stem assembly into the seat ring retainer (key 3) until the top of the plug stem seal assembly is even with the top of the seat ring retainer (key 3).

For NPS 4 balanced design, except Bore-seal trim, carefully insert the top end of the plug stem seal assembly into the bottom of the seat ring retainer (key 3) through the inner bore. Ensure no damage is done to the seals, as shown in figure 11. Slide the plug stem seal assembly into the seat ring retainer (key 3) until the top of the plug stem seal assembly is even with the top of the seat ring retainer (key 3). At this point, the plug (key 2) should have a snug fit with the seat ring retainer (key 3).

For NPS 4 balanced design Bore-seal trim, the valve plug, stem, plug retainer, Bore-seal, piston rings assembly is in a whole trim set with seat ring retainer, which is ready for step 6. See the NPS 4 Balanced Bore-seal Valve Plug Maintenance section.

6. Hold on to the end of the stem (key 7) and seat ring retainer (key 3) and slowly insert them into the valve body (key 1), as shown in figures 6, 7, 8, 12, 13, and 14. Be cautious and do not swing the assemblies, as the seat ring retainer (key 3) may fall off. At the same time, ensure that the seat ring retainer (key 3) bottom diameter is guided properly to the seat ring (key 9) when installed into the valve body (key 1).
7. After the plug (key 2), stem (key 7, figure 3), and seat ring retainer (key 4) assembly is placed into valve body (key 1), ensure one of the seat ring retainer legs centerline aligns with the valve body inlet centerline and the previous orientation mark between valve body (key 1, figures 6, 7, 8, 12, 13, and 14) and seat ring retainer (key 3, figures 6, 7, 8, 12, 13, and 14) aligns with each other. Once the seat ring retainer is oriented, gently push the plug seating surface against the seat ring (key 9). Note the plug stem assembly is symmetrical, so no orientation is necessary.

For NPS 4 balanced design Bore-seal trim, do not try to push the valve plug, plug retainer, stem, Bore-seal and piston rings assembly very hard into seat ring retainer Bore-seal sealing surface might require extra actuator force. Wait until the valve stem is attached to actuator therefore the actuator could push the Bore-seal plug into Bore-seal sealing surface.

8. Identify the spiral wound gasket (key 12) quantity per figures 6, 7, 8, 12, 13, and 14. Slide quantity 1 spiral wound gasket (key 12) per figures 6, 7, and 8, or quantity 3 spiral wound gaskets (key 12, figures 12, 13, and 14) and quantity 1 flat sheet gasket (key 10) over the seat ring retainer (key 3). Make sure the bottom of the gasket is flush with the mating surface on the seat ring retainer shoulder.
9. Coat the bonnet studs (key 15) with anti-seize lubricant (key 45) up to the deformed thread. Thread the studs into the valve body (key 1) by hand until the deformed thread prevents further insertion.
10. If no bonnet spacer is required for the construction, skip this step and go to step 11. Slide the bonnet spacer (key 32) onto the flat sheet gasket (key 10) over the seat ring retainer (key 3). Then, slide another flat sheet gasket (key 10) onto the bonnet spacer (key 32) over the seat ring retainer (key 3).
11. Mount the bonnet on the valve body and complete the assembly according to steps 10 through 14 of the packing replacement procedure.
12. Attach valve to actuator by securing the actuator yoke to valve bonnet with yoke locknut (key 15, figure 3, 4, or 5), and connecting valve stem to actuator stem connector per actuator instruction manual. Make sure the actuator stem and the valve stem are aligned with each other before connecting.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

CCV-N Valve

October 2018

Instruction Manual

D104191X012

CAUTION

Do not force the actuator to stroke the valve stem if actuator stem and valve stem are misaligned with each other, which might damage the valve trim and packing. Contact your [Emerson sales office](#) for further troubleshooting assistance.

Parts Ordering

Each body-bonnet assembly is assigned a serial number which can be found on the valve body. This same number also appears on the actuator nameplate when the valve is shipped from the factory as part of a control valve assembly. Refer to the serial number when contacting your [Emerson sales office](#) for technical assistance. When ordering replacement parts, refer to the serial number and to the eleven-character part number for each part required from the following parts kit or parts list information.

CAUTION

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Figure 1. Baumann 24000CVF Valve with
CML-250 Electric Actuator

Introduction

CML electric actuators (figure 1) provide high accuracy for industrial temperature, HVAC, and sanitary applications with Baumann sliding-stem control valves.

Scope of Manual

This instruction manual includes installation information for CML electric actuators.

Do not install, operate, or maintain CML electric actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Actuator Specifications

Table 1. CML Actuator Specifications

ACTUATOR	CML-250	CML-750
ACTUATOR HOUSING	Cast Aluminum	
ENVIRONMENTAL RATINGS	FM, CSA, ATEX, IEC	
OPTIONAL RATINGS	FM, CSA, ATEX, IEC	
STANDARD ENCLOSURE	FM NEMA 4 and 6 / IP67 Class 1 Div 1 Gr C, D Class II Div I E, F, G	
STANDARD TEMPERATURE RATING	-30°C to +70°C (-22°F to +158°F)	
HAZAROUS AREA TEMPERATURE RANGE	-20°C to +65°C (-4°F to +150°F)	
CONDUIT CONNECTION	3/4" - 14 NPT (M25 x 1.50p optional)	
MOTOR TYPE	Brushless DC	
OPTIONAL VOLTAGES	120VAC, 240VAC, 24VDC ⁽¹⁾	
STANDARD POWER	120VAC/240VAC	
THRUST RATING	250 lbs Mod/Run (1112.1 N) 375 lbs Seating (1668.1 N)	750 lbs Mod/Run (3336.2 N) 1125 lbs Seating (5004.2 N)
THRUST ADJUSTABILITY	60% - 150% Rated Thrust	
MAX SPEED	0.13 in/sec ⁽²⁾	
STANDARD CONTROL	Full range 4-20mA / Split Range 4/12 or 12-20mA **optional: 0-5Vdc and 0-10Vdc	
STANDARD FEEDBACK	4-20mA loop powered feedback ⁽³⁾	
STANDARD CONTROL OPTIONS (SPECIAL)	Discrete On/Off RIRO [24VDC or 120VAC control], HART, Foundation Fieldbus, DeviceNet, Profibus, Modbus, Pakscan	
HMI/GUI SETUP	LCD - text	
MODULATING DUTY CYCLE	Unrestricted and Continuous	
RESOLUTION	0.2% (adjustable deadband 0 - 10% of analogue signal)	
SENSITIVITY	0.2%	
RESPONSE TIME	20 milliseconds	
STANDARD FAILURE ACTION	Close valve / Open valve / Hold-in-Place / Fail to Position on loss of input signal (selectable). Holds in place on power failure (standard)	
CUSTOMER SETTINGS SAVED	Yes, Standard	
WEIGHT (ACTUATOR ONLY)	8.3 kg (18.4 lbs)	11.5 kg (25.4 lbs)
POWER BACK-UP OPTION	Available: Super Capacitors. Fail to Position on Loss of Power. Adjustable to Fail Closed, Fail Open, Fail to Position, Fail in Place	
LOWER CONTROL OPTION	Available: Separate option. Local controls come standard with Super Capacitor Power Back-up	

1. 24VAC not available.
2. Adjustable from 50 to 100%.
3. Includes 2 adjustable relay outputs.

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations to avoid personal injury.

Personal injury or property damage caused by sudden release of pressure or bursting of pressure retaining parts may result if service conditions exceed those for which the product was intended. To avoid injury or damage, provide a relief valve for over pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

This actuator is intended for a specific range of pressures, temperatures and other application specifications. Applying different pressures and temperatures to the actuator could result in parts damage, malfunction of the actuator or loss of control of the process. Do not expose this product to service conditions or variables other than those for which the product was intended. If you are not sure what these conditions are you should contact your [Emerson sales office](#) for more complete specifications. Provide the product serial numbers (shown on the nameplate) and all other pertinent information.

⚠ WARNING

If you move or work on an actuator installed on a valve with loading pressure applied, keep your hands and tools away from the stem travel path to avoid personal injury. Be especially careful when removing the stem connector to release all loading on the actuator stem.

Likewise take similar care when adjusting or removing any optional travel stop. Refer to the relevant actuator Maintenance Instructions.

If hoisting the valve, take care to prevent people from being injured in case the hoist or rigging slips. Be sure to use adequate sized hoists and chains or slings to handle the valve.

⚠ WARNING

Personal injury could result from packing leakage. Valve packing is tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

Educational Services

For information on available courses for CML electric actuators, as well as a variety of other products, contact:

Emerson Automation Solutions

emerson.com/fishervalvetraining

Maintenance

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Note

It is recommended that you review figure 2 before performing maintenance or installation of the CML electric actuator.

Recommended Installation Location

It is permissible to install the CML actuator upright or horizontally. Allow 12 inches of clearance for removal of the actuator. Do not install with the actuator below the pipe.

CAUTION

To avoid equipment damage, do not install the valve with the stem in a downward position. Equipment damage may occur from liquids leaking into the actuator cover.

9	Drive Nut
10	Packing Follower
12	O-Ring
14	Packing
27	Lock Nuts
49	Body Gasket
58	Travel Indicator

Installation

See table 2 for actuator parts/key numbers referenced in this Installation section. See table 3 and also refer to the appropriate Baumann valve instruction manual for valve parts referenced.

1. Before starting, ensure you have the correct actuator part number and locate the parts listed in table 2. Refer to the assembly instructions for the appropriate Baumann control valve for parts identification.
2. Place the valve body (key 1) in a vise. Clamp the flat end faces of the valve. DO NOT CLAMP THE SIDES OF THE VALVE. This may distort the shape of the casting and ruin the valve.
3. Push the valve stem (key 5) to the closed position. Install the two lock nuts (key 27) onto the stem (key 25).
4. Slowly lower the actuator down on the valve body (key 1). As the yoke (key 17) passes over the end of the valve stem (key 5), place the yoke drive nut (key 9) over the valve stem (key 5).
5. Screw the yoke drive nut (key 9) on to the bonnet (key 8) and tighten.
6. Place travel indicator disc (key 58) onto the valve stem (key 5).
7. For CML 750: Skip to step 10.
8. For CML 250: Remove the drive nut (supplied with actuator) from the base of the actuator and set the upper drive nut over the valve stem (key 5).
9. Place the spacer (key 68) on top of the actuator yoke (key 17) over the opening.
10. Set the actuator on top of the actuator yoke (key 17) and prepare for mounting
11. Lift the valve stem (key 5) with the travel indicator (key 58) and hold it. Spin the actuator onto top of the yoke (key 17) to screw the actuator stem onto the valve stem (key 5) by 9 full turns. The actuator should be facing forward when engagement is complete.

For the CML750 align the four bolt holes in the yoke (key 17) with the bolt holes in the actuator with the actuator facing forward.

12. For the CML 250 tighten the upper lock nut (supplied with actuator) on the actuator thread.

For the CML750 install the 4 cap screws (key 5) and tighten to 20 ft•lbs.

13. Raise the top lock nut (key 27) and lock travel indicator (key 58) on top. Then raise the lower lock nut (key 27) and lock in place to secure travel indicator (key 58) tight against the actuator stem.

Additional Calibration and Setup

Additional calibration and setup information is available:

Fisher™ 1B and 1BR Constant-Pressure Pump Governor Actuators

Figure 1. Fisher 1B Actuator on Direct-Acting easy-e™ Valve

W2232-1

Introduction

Scope of Manual

This instruction manual provides information on installation, adjustment, maintenance, and parts ordering for the Fisher 1B pump governor actuator. Refer to separate instruction manuals for information about the valve and other accessories used with these actuators.

Do not install, operate, or maintain a 1B pump governor actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

The 1B pump governor actuator (figure 1) is used to maintain a constant discharge pressure on steam driven turbine or reciprocating pumps and for pressure reducing or pressure relief applications. Typical pump governor applications include fire pumps, boiler feedwater pumps, and industrial or refining pumps where the discharge medium is oil, steam, air, or other noncorrosive fluid.

The 1BR pump governor actuator is combined with a push-down-to-open valve for service as a relief governor. A relief governor is used to divert excess pump discharge to the suction side of the pump.

Specifications

Table 1 provides specifications for the 1B and 1BR pump governor actuators.

Educational Services

Emerson Educational Services
Phone: +1-800-338-8158
E-mail: education@emerson.com
emerson.com/mytraining

Figure 2. Cylinder Connections

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Personal injury or equipment damage caused by sudden release of pressure may result if the valve assembly is installed where service conditions could exceed the limits given on the appropriate nameplates. To avoid such injury or damage, provide a relief valve for over-pressure protection as required by government or accepted industry codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

⚠ WARNING

When ordered, the valve configuration and construction materials were selected to meet particular pressure, temperature, pressure drop, and controlled fluid conditions. Responsibility for the safety of process media and compatibility of valve materials with process media rests solely with the purchaser and end-user. Since some valve body/trim material combinations are limited in their pressure drop and temperature ranges, do not apply any other conditions to the valve without first contacting your Emerson sales office.

The 1B pump governor can be installed either above or below the line but if possible it should be installed above it.

Note

Thoroughly clean and blow out all pipe scale and other foreign matter. It is recommended that a Fisher strainer be installed in the line ahead of the main valve to protect the governor while in service.

If continuous operation is desired during inspection or maintenance, install a conventional three-valve bypass around the governor.

Refer to figure 3.

1. Using good piping procedure install the governor with flow in the direction of the arrow cast on the valve body.
2. Run a 1/4 inch control line from the top of the governor to the side or top of the pump discharge line, about 10 feet from the pump. Install a pressure gauge and a large port needle valve in this line. Throttling this needle valve places a restriction in the control line to smooth out operation.

Figure 3. Fisher 1B Installation

AC4650

Note

Before putting the governor into operation, be sure to remove the plastic shipping plug in the vent hole of the adaptor piece.

3. Open the gate valve on the downstream side and close the valve in the bypass line.
4. Slowly open the upstream gate valve.
5. Allow the governor sufficient time to assume normal operation before checking the controlled pressure. If the governor is not controlling at the set point needed, make the necessary changes as directed in the section entitled Adjustments.

Adjustments

The pump governor has been factory set for the operating conditions stated in the order. To change the pump discharge, use the adjusting screw (key 3). To increase the discharge pressure, turn the adjusting screw into the yoke.

Pressure pulsation in the discharge line can be minimized by slightly closing the needle valve in the control line. Never completely close the needle valve while the pump governor is in operation.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced when necessary. The frequency of inspection and replacement depends on the severity of service conditions.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

When performing maintenance procedures, isolate the control valve from the process line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Use lock-out procedures to be sure that the above measures stay in effect while you are working on the actuator.

To Replace the Piston Cup:

1. Isolate the pump governor.
2. Remove the control line connection.
3. Unscrew the hex nuts (key 8).
4. Remove the cylinder cap (key 12).
5. Unscrew the cap screw (key 10) and remove the follower (key 6).
6. Remove the old piston cup (key 13) and install the new one.
7. Reassemble the pump governor in the following order: piston cup (key 13), follower (key 6), cap screw (key 10), cylinder cap (key 12), and hex nuts (key 8).

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always mention this number when corresponding with your [Emerson sales office](#) regarding technical information or replacement parts.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Fisher™ 262K Filter

Introduction

Scope of Manual

This manual provides instructions for installation, maintenance and parts information for Fisher 262K filters.

Do not install, operate, or maintain a Fisher 262K filter without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Product Description

The 262K filter is designed to remove dirt, scale, and other solid substances from the air supply to actuators and instruments.

The 262K filter is available with a cast iron (Style B) or stainless steel body (Style SSB) with NPT screwed connections. See table 1 for temperature capabilities.

The filter has a resin-impregnated cellulose filter element capable of capturing particles as small as 40 microns.

Figure 1. Typical Fisher 262K Filter

---	---

1. The pressure/temperature limits in this instruction manual and any applicable standard or code should not be exceeded.

2. A pressure exceeding this value can cause failure of, or leakage from, pressure-containing components.

Specifications

Specifications for the 262K filter are in table 1.

WARNING

Installation, operation, and maintenance procedures performed by unqualified personnel may result in unsafe operation. This condition may result in personal injury or equipment damage. Use qualified personnel when installing, operating, and maintaining this filter.

If a leak develops in the system, the escaping gas may accumulate and become a fire or explosion hazard. Immediately call qualified service personnel in case of trouble.

Installation

WARNING

Personal injury, equipment damage, or leakage due to escaping gas or bursting of pressure-containing parts may result if the filter is installed where its capabilities can be exceeded or where conditions exceed any ratings of the adjacent piping or piping connections. To avoid this, install a filter where:

- Service conditions are within unit capabilities.
- Service conditions are within applicable codes, regulations, or standards.
- Additionally, physical damage to the filter could result in breakage, causing personal injury and property damage due to escaping gas. To avoid such injury or damage, install the unit in a safe location.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

- If installing into an existing application, also refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

Using good piping practices, install the filter in the line with the flow in the direction of the arrow cast on the body. As shown in figure 2, when the 262K filter is mounted in a horizontal line, the filter element must be pointed down. When mounted in a vertical line, the filter element must also point down, with the flow passing from top to bottom.

Figure 3. Fisher 262K Filter

1980172-A

Maintenance

Filter parts are subject to normal wear and must be inspected periodically and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions and upon applicable codes and government regulations.

⚠ WARNING

Avoid personal injury or damage to property from sudden release of pressure or uncontrolled gas or other process fluid. Before starting disassembly, carefully release all pressures. Use a gauge to monitor pressure while releasing it.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Parts Ordering

When corresponding with your [Emerson sales office](#) about this filter, always reference the filter style (Cast iron, Style B; Stainless steel, Style SSB).

When ordering the repair kit, specify the complete 11-character part number from the following parts list.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Figure 1. Fisher 377 Trip Valve Mounted on Size 130 585C Actuator

W8435-1

Introduction

Scope of Manual

This instruction manual provides installation, operation, maintenance, and parts information for the Fisher 377 trip valve. Refer to separate instruction manuals for information regarding the control valve, actuator, and accessories.

Do not install, operate, or maintain a 377 trip valve without being fully trained and qualified in valve, actuator and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all of the contents of this manual, including all safety cautions and warnings. If you have any questions regarding these instructions contact your [Emerson sales office](#) before proceeding.

Description

377 pressure-sensing trip valves, shown in figures 1, 2, and 3, are for control applications where a specific valve/actuator action is required when supply pressure falls below a specific point. When supply pressure falls below the trip point, the trip valve cause the actuator to fail up, lock in the last position, or fail down. When the supply pressure rises above the trip point, the 377 trip valve automatically resets, allowing the system to return to normal operation. The trip valve can be top-mounted on a manifold, yoke-mounted, or bracket-mounted to match the application requirements. 377 trip valves are used with all types of piston actuators.

Figure 2. Typical Fisher 377 Trip Valve

W4292-1

Figure 3. Simplified Sectional View of Trip Valve

W4303-1

Specifications

Specifications for 377 trip valves are given in table 1.

Table 1. Specifications

Available Configurations

377 Trip Valve: Includes check valve, but no volume tank: user configured for locking position. For field use or replacement.

When supply pressure falls below the trip point,
377D Trip Valve: Fails actuator piston down. Includes check valve and volume tank.

377L Trip Valve: Locks actuator piston in the last position.

377U Trip Valve: Fails actuator piston up. Includes check valve and volume tank.

377CW Trip Valve: Fails fully clockwise to close valve. Requires check valve and volume tank. Trip valve moves piston to either up/down position and requires actuator configuration for actual clockwise movement.

377CCW Trip Valve: Fails fully counterclockwise to close valve. Requires check valve and volume tank. Trip valve moves piston to either up/down position and requires actuator configuration for actual counterclockwise movement.

All 377 Trip Valves can be converted to any of the above fail modes with minor hookup changes

Allowable Supply Pressure for Trip Valve⁽¹⁾

Maximum: 10.3 bar (150 psig)

Minimum: 3.8 bar (55 psig)

Outlet Pressure

Normal Operation: Pressure from control device

Fail-Up or Fail-Down Mode: Maximum volume tank pressure

Lock-In-Last-Position: Respective cylinder pressure

Trip Point⁽²⁾

Adjustable from a minimum of 2.8 bar (40 psig) to a maximum of 72 percent of supply pressure; see figure 4

Reset: 12.5 to 33 percent above adjusted trip point

Flow Coefficients (C_v)⁽³⁾

Depends on flow path (shown in figure 3) as follows:

Port A to Port B and Port D to Port E: 0.5

Port B to Port C and Port E to Port F: 0.6

Pressure Connections

1/4 NPT internal

Temperature Capabilities⁽¹⁾

Nitrile Diaphragms and O-Rings: -40 to 82°C (-40 to 180°F)

Fluorocarbon Diaphragms and O-Rings: -18 to 104°C (0 to 220°F)

Volume Tank Maximum Internal Working Pressure (for 377D, 377U, 377CW and 377CCW trip valves)

Standard: 10.3 bar (150 psig) for non-ASME approved applications. See note on page 7.

ASME Approved Applications: Rated 10.3 bar (150 psig), maximum; 9.3 bar (135 psig), recommended. See note on page 7.

Hazardous Area Classification

Complies with the requirements of ATEX Group II Category 2 Gas and Dust

Approximate Weight	Declaration of SEP
Trip Valve Aluminum: 0.95 kg (2.1 pounds) SST: 2.31 kg (5.1 pounds) Mounting Manifold: 0.5 kg (1.2 pounds) Volume Tank: Varies between 5.4 and 363 kg (12 and 800 pounds) depending on size	Fisher Controls International LLC declares this product to be in compliance with Article 4 paragraph 3 of the PED Directive 2014/68/EU. It was designed and manufactured in accordance with Sound Engineering Practice (SEP) and cannot bear the CE marking related to PED compliance. However, the product <i>may</i> bear the CE marking to indicate compliance with <i>other</i> applicable European Community Directives.
1. The pressure/temperature limits in this document and any applicable standard or code limitation should not be exceeded. 2. If the trip point is not specified, the trip point is factory set at 72 percent of supply pressure or 2.8 bar (40 psig), whichever is higher. 3. Values represent nominal C_v measures for each port pair using a trip valve/actuator combination.	

Figure 4. Maximum Trip Point Settings

NOTES:

- 1 > TRIP POINT MAY BE SET TO ANY VALUE BETWEEN 2.8 BAR (40 PSIG) AND THE MAXIMUM TRIP POINT LINE.
- 2 > RESET OCCURS AT 12.5 TO 33 PERCENT ABOVE ADJUSTED TRIP POINT.

Installation

⚠ WARNING

Avoid personal injury from sudden release of process pressure. Before mounting the controller:

- Always wear protective clothing, gloves, and eyewear when performing any installation operations to avoid personal injury.
- Overpressuring any system component could result in personal injury or property damage due to fire and explosion caused by venting or leakage of the supply medium. To avoid such injury or damage, provide suitable pressure-relief or pressure-limiting devices if the supply pressure is capable of exceeding the maximum allowable pressure of the system component.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.
- If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

NOTICE

Do not use sealing tape on pneumatic connections. This instrument contains small passages that may become obstructed by detached sealing tape. Thread sealant paste should be used to seal and lubricate pneumatic threaded connections.

The 377 trip valve is normally ordered as part of a control valve assembly. Follow the procedure in the appropriate valve body and actuator instruction manual when installing the control valve in the piping.

If the 377 trip valve is shipped separately from the control valve assembly, the installation procedure depends upon the type of actuator and accessory equipment required for the individual control valve system. Install any accessory equipment in the control valve system so that the overall functioning of the specified trip valve pressure line connections is not disrupted. Figures 7, 8, and 9 are schematics showing the pressure line connections for each of the three possible fail-mode configurations of the trip valve.

Note

377 trip valves are leak tested to ensure that the intended actuator fail mode is maintained upon loss of supply pressure. Control system accessories, such as volume boosters with hard seats, compromise the integrity of the entire system due to leakage. Therefore, using control system accessories, such as volume boosters, between the trip valve and the actuator is not recommended. If this cannot be avoided and a volume booster is required, a volume booster designed for tight shutoff, such as the Fisher 2625, provides a higher probability of control system integrity. Refer to figures 5 and 6 for proper installation of 377 trip valves with 2625 volume boosters.

Figure 5. Fisher 2625 Volume Booster used with 377U or 377D Trip Valve

NOTES:

1. THE HOOK UP OF PORT C AND F ARE REVERSED FOR 377D.

2. 3/4 NPT CHECK VALVE, 1/2 OR 3/4 NPT PIPING, AND 1/2-INCH (OUTSIDE DIAMETER) COIL TUBING FOR THE VOLUME TANK ARE REQUIRED.

3. THE SUPPLY PRESSURE REGULATOR SPECIFIED MUST HAVE ADEQUATE CAPACITY FOR 2625 BOOSTERS. ALSO, IF THE 2625 BOOSTER IS TO BE NIPPLE MOUNTED, THE BOOSTER MUST BE MOUNTED TO A 1/2 NPT OR LARGER CYLINDER CONNECTION. SOME SMALLER CYLINDERS CANNOT BE TAPPED THIS LARGE; CONTACT YOUR [EMERSON SALES OFFICE](#) FOR AVAILABILITY ON SPECIFIC TYPES AND SIZES.

E1570

Figure 6. Fisher 2625 Volume Booster used with 377L Trip Valve

NOTES:

1. 3/4 NPT CHECK VALVE AND 1/2 OR 3/4 NPT PIPING ARE REQUIRED.
2. THE SUPPLY PRESSURE REGULATOR SPECIFIED MUST HAVE ADEQUATE CAPACITY FOR 2625 BOOSTERS. ALSO, IF THE 2625 BOOSTER IS TO BE NIPPLE MOUNTED, THE BOOSTER MUST BE MOUNTED TO A 1/2 NPT OR LARGER CYLINDER CONNECTION. SOME SMALLER CYLINDERS CANNOT BE TAPPED THIS LARGE; CONTACT YOUR [EMERSON SALES OFFICE](#) FOR AVAILABILITY ON SPECIFIC TYPES AND SIZES.

E1571

Supply Pressure Requirements

⚠ WARNING

Severe personal injury or property damage may occur if the instrument air supply is not clean, dry, and oil free. While use and regular maintenance of a filter that removes particles larger than 40 micrometers in diameter will suffice in most applications, check with an Emerson field office and instrument industry air quality standards for use with corrosive gas or if you are unsure about the proper amount or method of air filtration or filter maintenance.

NOTICE

Do not use sealing tape on pneumatic connections. This instrument contains small passages that may become obstructed by detached sealing tape. Thread sealant paste should be used to seal and lubricate pneumatic threaded connections.

A supply regulator, if used, must have a flow capacity greater than the required combined capacity of the trip valve and actuator. In order to ensure proper selection of a supply regulator, be sure the C_v value of the regulator is greater than the appropriate flow path C_v value listed in table 1 for the trip valve. A regulator with insufficient capacity may allow supply pressure to droop, which can cause the trip valve to trip again and begin a trip-reset cycle. An example of an appropriate supply regulator to use with a 377 trip valve is a 64 regulator; its capacity is usually great enough to meet the demands of most trip valve/actuator combinations. Determine the requirements of your trip valve/actuator combination for proper selection of a supply regulator.

Note

During normal operation, an adequately sized supply regulator maintains a greater supply pressure than the pressure demand of the trip valve and control devices. However, if the normal actuator piston position is not relatively close to the actuator piston fail position during startup, or during the restoration of supply pressure, the regulator supply pressure may droop and cause the trip valve to trip again and begin a trip-reset cycle. To prevent this, perform the following steps:

1. Adjust the instrument (control device) pressure to position the actuator piston as it is positioned in the fail mode.
 2. Restore the supply pressure to the normal operating range.
 3. Manually reset the instrument pressure for normal operation.
-

WARNING

If a flammable or hazardous gas is used as the supply pressure medium, personal injury or property damage could result from fire or explosion of accumulated gas or from contact with hazardous gas. The positioner/ actuator assembly does not form a gas-tight seal, and when the assembly is enclosed, a remote vent line, adequate ventilation, and necessary safety measures should be used. However, a remote vent pipe alone cannot be relied upon to remove all hazardous gas. Vent line piping should comply with local and regional codes and should be as short as possible with adequate inside diameter and few bends to reduce case pressure buildup.

Note

To ensure trip system integrity upon loss of supply pressure, a 377D or 377U trip system requires a volume tank and check valve as shown in figures 7 and 9.

State and local regulations may require the use of ASME approved volume tanks. Determine requirements and applicable regulations for proper volume tank selection.

For ASME approved applications, the volume tank is rated at 10.3 bar (150 psig) internal working pressure, and has a safety valve with a 10.3 bar (150 psig) set pressure mounted on the volume tank for pressure relief. Avoid supply pressure too near the safety valve set pressure. To ensure safety valve seat tightness and longevity, the recommended maximum supply pressure is 9.3 bar (135 psig).

Standard volume tanks supplied in Europe must conform to Directive 2009/105/EC for simple pressure vessels. The maximum pressure rating is stated on the tank.

For standard applications (not ASME approved), a DOT tank is used. This tank is rated at 14.5 bar (240 psig) in LP service. When used with air, the rating should be considered to be 10.3 bar (150 psig), consistent with the maximum pressure allowed for the 377 trip valve.

1. Before installing the trip valve, inspect it to be sure it is free of any foreign material.
2. Be sure all connecting tubing is free of foreign material.
3. Use acceptable piping practices when installing the trip valve. Coat all external threaded connections with a pipe compound.

NOTICE

To avoid damage and possible operational impairment to the trip valve, be careful not to get excessive pipe compound on the connections. Excess compound could result in improper pilot and cylinder valve operation.

Note

To ensure the integrity of control systems utilizing a 2625 volume booster in conjunction with a 377 trip valve, apply supply pressure to the volume booster and to the volume tank (volume tank not required on 377L trip valve) through a check valve. Failure to install the check valve properly will allow the cylinder pressure to bleed back through the open volume booster supply port upon loss of supply pressure. The actuator may not fail as intended.

⚠ WARNING

Personal injury or property damage could result from bursting of parts due to temperature fluctuations or extreme heat. If temperature fluctuations or extreme heat cannot be avoided, use a relief valve to protect the volume tank.

4. Read the following information before making pressure connections:

- a. Trip valve port A must receive the operating pressure that is intended for the top of the actuator cylinder. Depending on the actuator type and accessories being used, this operating pressure will be from a valve positioner or switching solenoid.
- b. Trip valve port B must provide operating pressure to the top of the actuator cylinder. Depending on the actuator type and accessories being used, connect this port to the manifold assembly, to the top of the cylinder, or to the cylinder connection on the hydraulic snubber (if one is used).
- c. Trip valve port C must provide a fail-mode outlet for the operating pressure to or from the top of the actuator cylinder. For the fail-down mode, connect this port to the volume tank. For the fail-up mode, vent this port to atmosphere. For the lock-in-last-position mode, plug this port.
- d. Trip valve port D must receive the operating pressure that is intended for the bottom of the actuator cylinder. Depending on the actuator type and accessories being used, this operating pressure will be from a valve positioner or switching solenoid.
- e. Trip valve port E must provide operating pressure to the bottom of the actuator cylinder. Always connect this port to the bottom of the actuator cylinder.
- f. Trip valve port F must provide a fail-mode outlet for the operating pressure to or from the bottom of the actuator cylinder. For the fail-down mode, vent this port to atmosphere. For the fail-up mode, connect this port to the volume tank. For the lock-in-last-position mode, plug this port.

Operating Information

Calibration

This calibration procedure assumes that the trip valve is mounted on the actuator (or other device) and that all piping and the appropriate volume tank (if necessary) are installed. All key numbers refer to figure 10. For the appropriate fail-mode schematic, see figure 7, 8, or 9.

⚠ WARNING

The following procedure requires taking the trip valve out of service. To avoid personal injury and property damage by an uncontrolled process medium, provide some temporary means of control of the process medium while the trip valve is out of service.

1. Remove the adjusting screw cap (key 1).
2. Loosen the hex nut (key 3), and turn the set screw (key 2) counterclockwise until all loading is removed from the spring (key 6).
3. Connect an adequately sized gauge for the supply pressure reading to the supply line. To make the fail action more visible, adjust the control device signal so that actuator stem movement is visible when the trip valve is actuated.
4. For the lock-in-last-position mode, remove the plugs from ports C and F.
5. Set the supply pressure at the required trip point pressure (refer to table 1 for the trip point limits).

Note

For proper calibration, completely back out the set screw (key 2) until there is no spring compression. Then, set the trip point by turning the set screw clockwise to compress the spring.

6. Slowly turn the set screw clockwise to compress the spring until the trip valve trips. When the trip valve trips in the fail-up or fail-down mode, the actuator stem moves to the appropriate position. In the lock-in-last-position mode, the actuator stem does not move, however, air will be heard escaping from ports C and F. This is because pressure is being released from both sides of the actuator cylinder.
7. Tighten the hex nut (key 3), and install the adjusting screw cap (key 1).
8. For the lock-in-last-position mode, reinstall the plugs in ports C and F.
9. Reset the control device for normal operation.

Principle of Operation

377D Trip Valve

Figure 7 illustrates trip valve operation in the fail-down mode.

In normal operation, supply pressure loads the upper diaphragm of the trip valve. The valve plug spring keeps the exhaust port closed. Supply pressure also loads the lower diaphragm through the restriction, causing the plug assemblies to move down and isolate ports C and F while connecting port A to B and port D to E. Normal actuator control pressure from the control device is applied to the top of the cylinder through ports A and B and to the bottom of the cylinder through ports D and E. A volume tank is charged to the maximum supply pressure through a check valve. The check valve maintains maximum supply pressure in the volume tank if the supply pressure drops.

When the supply pressure falls below the trip point, the exhaust port opens venting the supply pressure that is loading the lower diaphragm. This causes the upper ports of the plug assemblies to close and disconnect normal pressure from the control device to the actuator.

Volume tank pressure is then applied through ports C and B to the top of the actuator cylinder, while pressure in the bottom of the actuator cylinder is vented through ports E and F. The pressure imbalance created forces the actuator piston down.

When supply pressure is restored, it again loads the upper and lower diaphragms causing the trip valve to reset. The exhaust port closes, the upper ports of the plug assemblies open, and the lower ports close. Normal actuator control pressure from the control device is restored through ports A and B and ports D and E. The check valve opens and recharges the volume tank to the maximum supply pressure.

Figure 7. Fisher 377D Trip Valve Shown in Tripped Condition

GE08412-A
A6905-1

377L Trip Valve

Figure 8 illustrates trip valve operation in the lock-in-last-position mode.

When supply pressure falls below the trip point, the exhaust port opens venting supply pressure from the lower diaphragm. This causes the upper ports of the plug assemblies to close and the lower ports to open. Because ports C and F are plugged, no pressure change occurs on either side of the actuator piston and the piston is pressure-locked in position. No volume tank is necessary in this mode.

When supply pressure is restored, the plug assemblies move back into the normal operating position. Supply pressure from the control device is applied to the actuator through ports A and B and ports D and E.

Figure 8. Fisher 377L Trip Valve Shown in Tripped Condition

GE08414-A
A6906-1

377U Trip Valve

Figure 9 illustrates trip valve operation in the fail-up mode. The fail-up mode of operation is similar to the fail-down mode of operation except that the connections to port C and F are reversed. When supply pressure falls below the trip point, the top of the actuator cylinder vents, and volume tank pressure loads the bottom of the actuator cylinder. The pressure imbalance created forces the actuator piston up.

Figure 9. Fisher 377U Trip Valve Shown in Tripped Condition

GE08413-A
A2284-6

Maintenance

Trip valve parts are subject to normal wear so the trip valve must be actuated periodically to determine if it is working properly. If the trip valve does not work properly, use the following procedures to inspect and repair or replace parts as necessary. The frequency of inspection and repair or replacement depends upon the severity of service conditions. Be sure to note the location of all pressure connections to ensure proper trip valve installation upon reassembly, or use the installation procedures in this instruction manual. All key numbers refer to figure 10 unless otherwise indicated.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Always wear protective clothing, gloves, and eyewear when performing any maintenance operations to avoid personal injury.
- Do not remove the actuator from the valve while the valve is still pressurized.

- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Periodic Operational Check

⚠ WARNING

The following procedure requires taking the trip valve out of service. To avoid personal injury and property damage by uncontrolled process medium, provide some temporary means of control of the process medium while the trip valve is out of service.

1. Isolate the actuator/valve assembly from the process loop.
2. Provide a means of monitoring the supply pressure input to the trip valve.
3. Starting with normal supply pressure applied to the trip valve, slowly reduce the supply pressure until the trip valve trips. The trip valve should trip at the pressure set during the calibration procedures.
4. Increase the supply pressure until the trip valve resets. This should occur at a supply pressure 12.5 to 33 percent above the trip point.
5. If the trip valve fails to trip and reset at the calibrated settings, refer to the calibration procedures.
6. If the trip valve will not calibrate, continue with the following maintenance procedures.

Trip Valve Part Replacement Procedures

⚠ WARNING

Refer to the **WARNING** at the beginning of the Maintenance Section in this instruction manual.

Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

Replacing Diaphragms and Valve Plug Parts

NOTICE

Care must be taken during the following procedure to prevent damage to the upper diaphragm.

1. Remove the adjusting screw cap (key 1), and loosen the hex nut (key 3) that locks the set screw (key 2). Loosen the set screw to remove all spring compression.
2. Remove the cap screws (key 7, not shown) from the spring case, and lift off the body assembly (key 16) and attached parts from the trip valve body (key 21). Note the orientation of the vent and supply connections to the body (see figure 1).
3. Remove the cap screws (key 20, not shown) and separate the diaphragm (key 17), diaphragm spacer (key 19), and the pusher plate (key 18) from the rest of the body assembly. Lift off the spring case (key 4), travel stop (key 75, aluminum housing only), upper spring seat (key 5), and spring (key 6).
4. Take out the upper diaphragm assembly (keys 8, 9, 10, 11, 12, 13, 14, and 15).
5. Carefully unscrew the spring seat (key 9) from the upper diaphragm retainer (key 13). Be careful not to lose the valve plug (key 14), valve guide (key 8), and spring (key 10). Also be careful not to damage the upper diaphragm (key 12).
6. Inspect the upper diaphragm, valve plug, body assembly, and O-ring (key 15) for nicks, scratches, or cuts that could cause leakage. Replace parts as necessary. Make sure the O-ring (key 15) is properly lubricated (key 77) to avoid leakage past the O-ring.
7. With the spring (key 10), spring seat (key 9), valve plug (key 13), valve guide (key 8), diaphragm washer (key 11), and upper diaphragm (key 12) in place, screw the upper diaphragm retainer (key 13) and spring seat (key 9) together, being careful not to damage the diaphragm.
8. Inspect the lower diaphragm (key 17) and pusher plate (key 18), and replace them if damaged or excessively worn.
9. Place the upper diaphragm assembly (keys 8, 9, 10, 11, 12, 13, 14, and 15), travel stop (key 75, aluminum housing only), spring (key 6), upper spring seat (key 5), diaphragm spacer (key 19), pusher plate (key 18), and diaphragm (key 17) onto the body assembly (key 16). Secure the body assembly parts to the spring case (key 4) with the cap screws (key 20). Position the supply and vent connections as noted in step 2.
10. Note the orientation of the supply connection to the body (see figure 1). Attach the assembly, from step 9, to the body (key 21) with the cap screws (key 7, not shown). Tighten the screws.
11. Refer to the installation and calibration procedures.

Replacing Stem/Plug Assembly Parts

1. Remove the cap screws (key 76, not shown) from the body (key 21), and remove the manifold (key 73) and the stem/plug assemblies (keys 22, 23, 24, 26, and 27).
2. Inspect the upper and lower O-rings (keys 23 and 26) for nicks or wear. If the lower O-ring needs to be replaced, remove the O-ring retainer screw (key 27) before installing the new O-ring. The upper O-ring simply slips over the end of the stem (key 22). Lightly lubricate O-rings (key 77) prior to reassembly.
3. Inspect the stem/plug assemblies, inspect the valve seats in the body (key 21), and replace any parts if necessary.
4. When stem/plug assembly maintenance procedures are complete, carefully slide the stem/plug assemblies (keys 22, 23, 24, 26, and 27) and springs (key 25) into the body. Attach the manifold (key 73) to the bottom of the body (key 21), and tighten the screws (key 76).
5. Refer to the installation and calibration procedures.

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, always refer to the trip valve serial number which is located on the nameplate. Refer to table 2 for common parts. Contact your Emerson sales office if part numbers are needed.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher trip valve. Use of components not supplied by Emerson may void your warranty, might adversely affect the performance of the instrument, and could cause personal injury and property damage.

Parts Kits

Description	Part Number
Repair Kit	
Kit include valve plugs, stems, plug assemblies, and nitrile diaphragms, O-rings, and gasket (keys 12, 14, 15, 17, 22, 23, 24, 26, 29, 63, 74, and 89).

Figure 1. Fisher 461 Valve with 657 Actuator

W9553-2

Introduction

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for the Fisher 461 anti-choke valve. Refer to separate manuals for instructions covering the actuator, positioner, and accessories.

Description

The 461 valve (figure 1) is a self-cleaning, increased-outlet, angle valve that is typically used in the chemical and hydrocarbon industries where control of residual oils or other liquids with choking properties is necessary. The 461 features a venturi-type throat, which is useful in power plants or slurry services where high pressure drops and flashing might exist.

Do not install, operate, or maintain a 461 valve without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Table 1. Specifications

Valve Sizes (inlet size x outlet size) NPS ■ 2x3, ■ 3x4, ■ 4x6, and ■ 6x8 Shutoff Classification per ANSI/FCI 70-2 and IEC 60534-4 Standard: Class IV Optional: Class V	Flow Characteristic Equal percentage Micro-Form flow characteristic in the 12.7 to 31.8 mm (0.5 to 1.25 inch) port size and a modified parabolic flow characteristic in the 38.1 to 114.3 mm (1.5 to 4.5 inch) port size Flow Direction Flow down Packing Arrangement PTFE and graphite ribbon/filament are available as standard packing
---	---

Specifications

Specifications for the 461 valve are shown in table 1. If the valve is shipped with the actuator, some of the valve specifications are on the valve nameplate, which is attached to the actuator. If the valve is shipped without the actuator, the valve nameplate is wired to the valve.

Installation

WARNING

To avoid personal injury or equipment damage caused by sudden release of pressure, install the valve assembly only where service conditions will not exceed the limits given on the appropriate nameplate.

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

1. Before installing a 461 valve, inspect it for any foreign material that may have collected during crating or shipping.
2. Check that the pipelines are free of pipe scale, chips, welding slag, and other foreign material.
3. Use accepted piping practices when installing the valve.
4. Do not install the valve in a system where the service conditions exceed those specified when the valve was ordered.
5. If continuous operation is required during maintenance and inspection, install a three-valve bypass around the valve body so that it will be isolated.
6. Orient the valve body so that the flow will be in the direction indicated by the flow direction arrow located on the outside of the valve body to ensure proper self-cleaning action.
7. If the actuator and valve are shipped separately, refer to the actuator mounting procedure outlined in the appropriate actuator instruction manual.
8. If the valve body was shipped without packing installed in the packing box, install the packing before putting the valve body into service. Refer to instructions given in the Packing Maintenance procedure.

WARNING

Personal injury could result from packing leakage. Valve packing was tightened before shipment; however, the packing might require some readjustment to meet specific service conditions.

Valves with ENVIRO-SEAL™ live-loaded packing or HIGH-SEAL Heavy-Duty live-loaded packing will not require this initial re-adjustment. See the instruction manuals titled ENVIRO-SEAL Packing System for Sliding-Stem Valves, [D101642X012](#), or HIGH-SEAL Live-Loaded Packing System, [D101453X012](#), (as appropriate) for packing instructions. If you wish to convert your present packing arrangement to ENVIRO-SEAL packing, refer to the retrofit kits listed in the parts kit sub-section near the end of this manual.

Maintenance

Valve parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Note

If the valve has ENVIRO-SEAL live-loaded packing installed (figure 4), see the instruction manual entitled ENVIRO-SEAL Packing System for Sliding-Stem Valves, [D101642X012](#), for packing instructions.

If the valve has HIGH-SEAL Heavy-Duty live-loaded packing installed (figure 4), see the instruction manual entitled HIGH-SEAL Live-Loaded Packing System, [D101453X012](#), for packing instructions.

Figure 2. Lubricator and Lubricator/Isolating Valve

10A9421-A
AJ5428-D
A0832-2

Packing Lubrication

Note

To avoid lubricants breaking down at elevated temperatures, do not lubricate packing used in processes with temperatures over 260°C (500°F).

⚠ WARNING

Do not lubricate parts when used in oxygen service, or where the lubrication is incompatible with the process media. Any use of lubricant can lead to the sudden explosion of media due to the oil/oxygen mixture, causing personal injury or property damage.

If a lubricator or lubricator/isolating valve (figure 2) is provided for PTFE/composition or other packings that require lubrication, it will be installed in place of the pipe plug (key 12, figure 6). Use a good quality silicon-base lubricant. Packing used in oxygen service or in processes with temperatures over 260°C (500°F) should not be lubricated. To operate the lubricator, turn the cap screw clockwise to force the lubricant into the packing box. The lubricator/isolating valve operates the same way except the isolating valve must first be opened and then closed after lubrication is completed.

Packing Maintenance

If there is undesirable packing leakage in the spring-loaded PTFE V-ring packing shown in figure 3, tighten the packing flange nuts (key 25, figure 6) until the shoulder on the packing follower (key 29, figure 6) contacts the bonnet (key 14, figure 6). If leakage continues, replace the packing by following the numbered steps presented in the replacing packing procedure.

If there is undesirable packing leakage with other than spring-loaded PTFE V-ring packing, first try to limit the leakage and establish a stem seal by tightening the packing flange nuts (key 25, figure 6) to at least the minimum recommended torque in table 2 or 3. However, do not exceed the maximum recommended torque in table 2 or 3 or excessive friction may result. If leakage continues, replace the packing by following the numbered steps presented in the Replacing Packing procedure.

If the packing is relatively new and tight on the valve plug stem, and if tightening the packing flange nuts does not stop the leakage, it is possible that the stem is worn or nicked so that a seal cannot be made. The surface finish of a new stem is critical for making a good packing seal. If the leakage comes from the outside diameter of the packing, it is possible that the leakage is caused by nicks or scratches around the packing box wall. While replacing the packing according to the Replacing Packing procedure, inspect the valve plug stem and packing box wall for nicks or scratches.

Adding Packing Rings

Key numbers referred to in this procedure are shown in figure 6, unless otherwise indicated.

When using packing with a lantern ring, it may be possible to add packing rings above the lantern ring as a temporary measure without removing the actuator from the valve body.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. Remove the packing flange nuts (key 25) and lift the packing flange, upper wiper, and packing follower (keys 23, 16, and 29) away from the valve body.
3. It may be possible to dig out the old packing rings on top of the lantern ring, but use care to avoid scratching the valve plug stem or packing box wall. Clean all metal parts to remove particles that would prevent the packing from sealing.
4. Remove the stem connector and slip the packing rings over the end of the valve plug stem.
5. Reassemble the packing follower, upper wiper, packing flange, and packing flange nuts (keys 29, 16, 23, and 25).
6. Reconnect the body-actuator stem connection according to the appropriate actuator instruction manual.
7. Tighten the packing flange nuts only far enough to stop leakage under operating conditions. Check for leakage around the packing follower when the valve is being put into service. Retighten the packing flange nuts as required (see table 2 or 3).

Replacing Packing

WARNING

Refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

Key numbers referred to in this procedure are shown in figure 6, unless otherwise indicated.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. Remove the cap screws in the stem connector, and separate the two halves of the stem connector. Then exhaust all actuator pressure, if any was applied, and disconnect the actuator supply and any leakoff piping.

Figure 3. Packing Arrangements

NOTES:

- 1 0.102 mm (0.004 INCH) THICK SACRIFICIAL ZINC WASHERS. USE ONLY ONE BELOW EACH GRAPHITE RIBBON RING.
- 2 HAS THE APPEARANCE OF A WOVEN OR BRAIDED RING.
- 3 FOR A FLAT BOTTOM PACKING BOX, THESE PARTS ARE NOT NEEDED.

C0747-1

Figure 4. ENVIRO-SEAL and HIGH-SEAL Packing Systems

TYPICAL ENVIRO-SEAL PACKING SYSTEM WITH GRAPHITE ULF PACKING

W8533-1

TYPICAL HIGH-SEAL PACKING SYSTEM WITH GRAPHITE ULF PACKING

W7018

TYPICAL ENVIRO-SEAL PACKING SYSTEM WITH DUPLEX PACKING

1 FOR A FLAT BOTTOM PACKING BOX, THE PACKING BOX RING AND LOWER WIPER ARE NOT NEEDED.

3. Remove the yoke locknut (key 26), and remove the actuator from the bonnet (key 14).
4. Loosen the packing flange nuts (key 25) so that the packing is not tight on the valve plug stem (key 10). Remove any travel indicator disk and stem locknuts from the valve plug stem threads.

NOTICE

When lifting the bonnet (key 14), be sure that the valve plug and stem assembly (keys 3 and 10) remains on the seat ring (key 2). This avoids damage to the seating surfaces as a result of the assembly dropping from the bonnet after being lifted part way out. The parts are also easier to handle separately. Use care to avoid damaging gasket sealing surfaces.

⚠ WARNING

To avoid personal injury or property damage caused by uncontrolled movement of the bonnet, loosen the bonnet by following the instructions in the next step. Do not remove a stuck bonnet by pulling on it with equipment that can stretch or store energy in any other manner. The sudden release of stored energy can cause uncontrolled movement of the bonnet. If the liner sticks to the bonnet, proceed carefully with bonnet removal and support the liner so that it will not fall unexpectedly from the bonnet.

Note

The following step also provides additional assurance that the valve body fluid pressure has been relieved.

5. Hex nuts (key 8) attach the bonnet to the valve body. Loosen these nuts approximately 3 mm (1/8 inch). Then loosen the body-to-bonnet gasketed joint by either rocking the bonnet or prying between the bonnet and valve body. Work the prying tool around the bonnet until the bonnet loosens. If no fluid leaks from the joint, proceed to the next step.
6. Unscrew the hex nuts (key 8) and carefully lift the bonnet off the valve stem. If the valve plug and stem assembly starts to lift with the bonnet, use a brass or lead hammer on the end of the stem and tap it back down. Set the bonnet on a cardboard or wooden surface to prevent damage to the bonnet gasket surface.
7. Remove the valve plug (key 3), bonnet gasket (key 6) and the liner (key 5).

⚠ WARNING

To avoid personal injury or property damage caused by process media leakage, inspect the liner, bonnet, and body gasket surfaces to ensure they are in good condition, with all foreign material removed. Small burrs less than approximately 0.076 mm (0.003 inches) in height (the thickness of a human hair) can be ignored. Scratches or burrs that run across the serrations are not permitted under any conditions, because they will prevent the gaskets from sealing properly.

8. Clean all gasket surfaces with a good wire brush. Clean in the same direction as the surface serrations, not across them.
9. Cover the opening in the valve body to protect the gasket surface and to prevent foreign material from getting into the valve body cavity.
10. Remove the packing flange nuts (key 25), packing flange (key 23), upper wiper (key 16), and packing follower (key 29). Carefully push out all the remaining packing parts from the valve side of the bonnet using a rounded rod or other tool that will not scratch the packing box wall.

Figure 5. Installing Graphite Ribbon/Filament Packing Rings One at a Time

A2207-2

11. Clean the packing box and the following metal packing parts: packing follower, packing box ring, spring or lantern ring, and, for single arrangements of PTFE V-ring packing only, special washer (key 18).
12. Inspect the valve stem threads for any sharp edges that might cut the packing. A whetstone or emery cloth may be used to smooth the threads if necessary.
13. Remove the protective covering from the valve body cavity, and install the liner. Install the plug and position the new bonnet gasket (key 6) on top of the valve body. Then slide the bonnet over the stem and onto the studs (key 7).

Note

The prelubricated hex nuts (key 8) referred to in step 14 can be identified by a black film coating on the nut threads.

The proper bolting procedures in step 14 include--but are not limited to--ensuring that the bonnet stud threads are clean, and that the hex nuts are evenly tightened to the specified torque values.

NOTICE

Failure to comply with good bonnet-to-body bolting practices and the torque values shown in table 4 may result in damage to the valve. Cheater bars or slug wrenches should not be used for this procedure.

Hot torquing is not recommended.

14. Lubricate the stud threads, nut threads, and the faces of the hex nuts (key 8) with anti-seize lubricant (not necessary if new factory prelubricated hex nuts are used). Replace the hex nuts and tighten them finger-tight. Stroke the valve several times to center the trim. Torque the nuts in a crisscross pattern to no more than 1/4 of the nominal torque value specified in table 4.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

461 Valve

January 2023

Instruction Manual

D100714X012

When all nuts are tightened to that torque value, increase the torque by 1/4 of the specified nominal torque and repeat the crisscross pattern. Repeat this procedure until all nuts are tightened to the specified nominal value. Apply the final torque value again and, if any nut still turns, tighten every nut again.

Note

When installing packing rings, prevent entrapping air between the rings. Add the rings one at a time without forcing them below the chamfer of the packing box entrance chamber. As each successive ring is added, the stack should not be pushed down more than the thickness of the added ring (figure 5).

15. Install new packing and the metal packing box parts according to the appropriate arrangement in figure 3. If desired, packing parts may be pre-lubricated with a silicon base grease for easier installation. Slip a smooth-edged pipe over the valve stem, and gently tamp each soft packing part into the packing box, being sure that air is not trapped between adjacent soft parts.
16. Slide the packing follower, wiper, and packing flange into position. Lubricate the packing flange studs (key 24) and the faces of the packing flange nuts (key 25). Replace the packing flange nuts.

For the spring-loaded PTFE V-ring packing shown in figure 3, tighten the packing flange nuts until the shoulder on the packing follower (key 29) contacts the bonnet.

For graphite packing, tighten the packing flange nuts to the maximum recommended torque shown in table 2. Then, loosen the packing flange nuts, and retighten them to the recommended minimum torque shown in table 2.

For other packing types, tighten the packing flange nuts alternately in small equal increments until one of the nuts reaches the minimum recommended torque shown in table 3. Then, tighten the remaining flange nuts until the packing flange is level and at a 90-degree angle to the valve stem.

For ENVIRO-SEAL or HIGH-SEAL live-loaded packing, refer to the note at the beginning of the Maintenance section.

17. Mount the actuator on the valve body assembly, and reconnect the actuator and valve plug stems according to the procedures in the appropriate actuator instruction manual.

Table 2. Recommended Torque for Graphite Type Packing Flange Nuts (Non Live-Loaded)

VALVE STEM DIAMETER		PRESSURE RATING	TORQUE			
			N•m		lbf•ft	
mm	Inches		Min	Max	Min	Max
19.1	3/4	CL600	21	31	15	23
		CL900	27	41	20	30

		CL1500	68	102	50	75
		CL2500	81	122	60	90

Replacing Trim

Refer to figure 6.

Disassembly

1. Remove the actuator and the bonnet according to steps 1 through 6 of the Replacing Packing section.
2. Remove the valve plug and stem assembly (keys 3 and 10) from the valve. If the stem needs to be replaced, drive the pin (key 11) out, and unthread the stem from the plug.

NOTICE

Never use an old stem with a new valve plug. The use of an old stem requires drilling a new pin hole through the stem, which will weaken the stem.

3. If the valve plug needs replacing, replace the entire valve plug and stem assembly. Do not reuse the old stem on a new valve plug. If only a new stem is necessary, screw the plug onto the new stem. Drill a 4.8 mm (3/16 inch) hole through the stem using the plug pin hole as a guide. Drive the pin into the stem and plug.

Table 3. Recommended Torque for PTFE Type Packing Flange Nuts (non live-loaded)

VALVE STEM DIAMETER		PRESSURE RATING	TORQUE			
			N•m		lbf•ft	
mm	Inches		Min	Max	Min	Max
19.1	3/4	CL600	10	15	7	11
		CL900	27	41	20	30
		CL1500	34	50	25	37
		CL2500	41	61	30	45
25.4	1	CL600	17	25	13	18
		CL900	42	62	31	46
		CL1500	52	77	38	57
		CL2500	61	91	45	67
31.8	1-1/4	CL600	24	36	18	27
		CL900	56	83	41	61
		CL1500	68	102	50	75
		CL2500	81	122	60	90

4. With the stem and valve plug assembly removed, slide the liner (key 5) out of the valve body. Inspect the seat ring (key 2) for nicks and scratches. Make sure the valve plug and seat ring contact surfaces are free of nicks and scratches.
5. To remove the liner (key 5), break it loose by using cap screws in the tapped holes located in the liner's flange. (In some very hard materials, i.e., R30006, the holes have been omitted; therefore, a sleeve puller or similar device must be used).
6. To replace the seat ring (key 2), remove the valve from the line, or remove the pipe connected to the flange. Then, unthread the seat ring retainer (key 4), and remove the seat ring through the bottom of the valve body.

Assembly

1. When assembling, use a new bonnet gasket (key 6), and wipe all sealing surfaces (valve body, bonnet, and gaskets) with a clean cloth. If the seat ring (key 2) was removed, install it in the valve body (key 1), and then torque the seat ring retainer (key 4) into the valve body. Because there is no gasket between the seat ring and the valve body, make sure that the mating surfaces are clean and free of nicks and scratches.
2. Replace the liner (key 5). Then, slide the valve plug and stem assembly (keys 3 and 10) into the valve body (key 1).

3. Mount the bonnet (key 14) onto the valve body (key 1), being careful not to damage the gasket.

Note

If the seating surfaces of the valve plug and seat ring require lapping, refer to the Lapping Seating Surfaces section before continuing to assemble the valve.

NOTICE

Avoid product damage in the following step by taking care not to damage the packing while installing the bonnet.

4. If it is necessary to replace the packing, perform steps 10 through 16 of the Replacing Packing section. However, if it is not necessary to replace the packing, make sure to install the bonnet carefully on the valve body to avoid damaging the packing with the valve stem threads.
5. Lubricate the valve body studs and nuts (key 7) with anti-seize lubricant, and install the nuts (key 8) on the bolts. Tighten the nuts in a crisscross pattern to no more than 1/4 of the nominal torque value specified in table 4 to ensure a positive seal and even pressure on the bonnet.

When all nuts are tightened to that torque value, increase the torque by 1/4 of the specified nominal torque and repeat the crisscross pattern. Repeat this procedure until all nuts are tightened to the specified nominal value. Apply the final torque value again and, if any nut still turns, tighten every nut again.

Note

It may be necessary to repeat the bolting pattern several times until the bonnet-to-body seal is made since the tightening of one nut might loosen an adjacent nut. It is recommended that the pattern be repeated until none of the nuts will turn at the recommended torque.

6. Mount the actuator on the bonnet, and make up the stem connection according to the procedure given in the appropriate actuator instruction manual.

Lapping Seating Surfaces

A certain amount of leakage should be expected with metal-to-metal seating in any valve body. If the leakage becomes excessive, however, the condition of the seating surfaces of the valve plug and seat ring can be improved by grinding. Large nicks should be machined out rather than ground out. Use a commercial lapping compound or a mixture of 600-grit Carborundum and solidified vegetable oil. Apply the compound to the bottom of the valve plug, and apply white lead to the seat ring to prevent excessive tearing or cutting during lapping. The white lead should not be mixed with the grinding compound, but rather applied separately.

The valve must be assembled to the extent that the valve plug and stem assembly (keys 3 and 10) and the seat ring (key 2) are in place and the bonnet (key 14) is bolted to the valve body (key 1). A simple handle can be made from a piece of strap iron locked to the valve plug stem with nuts. Rotate the handle alternately in each direction to lap the seats. After lapping, remove the bonnet, and clean the seating surfaces. Completely assemble as described in the Assembly part of the Maintenance section, and test the valve for shutoff. Repeat the lapping procedure if leakage is still excessive.

Parts Ordering

Each body-bonnet assembly is assigned a serial number, which is on the body nameplate. The serial number also appears on the actuator nameplate if you bought a valve and actuator assembly. Refer to this serial number when contacting your [Emerson sales office](#) for technical advice. When ordering replacement parts, mention this serial number. Also specify key number and part description following Parts List.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts List

Note

Contact your Emerson sales office for Part Ordering information.

Key Description

Introduction

Scope of Manual

This instruction manual provides installation, maintenance, and parts information for Fisher 480 Series yokeless piston actuators.

Do not install, operate, or maintain 480 Series actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

Description

480 Series actuators (figure 1) are yokeless piston actuators that are used in either throttling or on/off applications with ball valves, butterfly valves, louvers, dampers, and rheostats. They require pneumatic pressure loading from double-acting positioners (Fisher 3570) or from on/off loading and unloading devices.

Specifications

Table 1 lists specifications for the 480 Series actuator and table 3 lists specifications for the 3570 actuator.

Table 1. Fisher 480 Series Actuator Specifications

Available Configurations See the Actuator Configurations section. Cylinder Pressure Maximum Allowable:⁽⁴⁾ 10.3 bar (150 psig) Required to Produce a Given Thrust: See figure 2 Minimum Recommended: Valves with low torque requirements -- (2.4 bar [35 psig]); all other valves -- (3.4 bar [50 psig]) Maximum Supply Source Consumption With Positioner and Constant Input Signal: 0.54 normal m³/hr⁽¹⁾ (20 scfh⁽¹⁾) of air at 6.9 bar (100 psig) Without Positioner: Depends on cylinder volume and supply pressure Travel Information Maximum Rated Travels, All 480 Series actuators with Linear Output: See table 2 Travel Stops Available for 480 Series actuators with 105 mm (4.125 inch) Maximum Rated Travels: See table 2 Thrust Information See figure 2 Torque Output 480, 480-15, and 480-16 (for butterfly valves): Contact your Emerson sales office or Local Business Partner	Stroking Speeds See table 2 Operative Ambient Temperature⁽²⁾ With Nitrile O-Rings: -46 to 80°C (-50 to 175°F) With Fluorocarbon O-Rings (Optional):⁽³⁾ -18 to 149°C (0 to 300°F) Actuator Size and Piston Size See table 2 Pressure Connections Standard is 1/4 NPT. For larger sizes, contact your Emerson sales office. Construction Materials Actuator: <table border="1"> <thead> <tr> <th>Part</th><th>Material</th></tr> </thead> <tbody> <tr> <td>Cylinder and Piston</td><td>Aluminum</td></tr> <tr> <td>Piston Rod Extension</td><td>SST, Chrome Plated</td></tr> <tr> <td>Cylinder Seal Bushings</td><td>Brass</td></tr> <tr> <td>O-Rings</td><td>Nitrile or Fluorocarbon</td></tr> </tbody> </table> Options ■ 376 Series trip valve system to fail actuator ■ up or ■ down or ■ lock in last position ■ TopWorx™ DXP M21GNEB electrical valve stem position switch ■ Micro-Switch limit switches	Part	Material	Cylinder and Piston	Aluminum	Piston Rod Extension	SST, Chrome Plated	Cylinder Seal Bushings	Brass	O-Rings	Nitrile or Fluorocarbon
Part	Material

Piston Rod Extension	SST, Chrome Plated										
Cylinder Seal Bushings	Brass										
O-Rings	Nitrile or Fluorocarbon										

1. Normal m³/hr. - normal cubic meters per hour (0°C and 1.01325 bar, absolute); Scfh - standard cubic feet per hour (60°F and 14.7 psia).

2. These terms are defined in ANSI/ISA Standard 551.1

3. Without snubber. If this actuator has a snubber, the temperature specification is the same for the nitrile version.

4. The pressure limits in this bulletin and any applicable standard or code limitation for actuator should not be exceeded.

Table 2. Size, Piston, Stroking Speed, and Travel Information

ACTUATOR SIZE	EFFECTIVE PISTON AREA		PISTON DIAMETER		STROKING SPEED ⁽¹⁾		SINGLE-FLANGE				TRAVEL STOPS AVAILABLE FOR ACTUATORS WITH 105 mm (4.125 INCHES) MAXIMUM RATED TRAVEL	
							-16 Versions		All Others Except Fisher 487, 487-1 ⁽²⁾

40	182	28.25	156	6.125	52	2.05	206	8.125	105	4.125	89	3.5
60	258	55.5	216	8.5	33	1.30						
1. For actuators with positioners at 6.9 bar (100 psig) supply pressure and all prestroke conditions satisfied. Stroking speeds for actuators without positioners or with snubbers will depend on the particular construction involved. 2. See 480 series Actuators Specifications for these travels.												

Table 3. Fisher 3570 Actuator Specifications

Available Configurations

3570: Valve positioner with two relays and three pressure gauges for monitoring input signal and output pressures to the top and underside of the actuator piston

3570C: Similar to 3570 except that the positioner is equipped with automotive tire valves instead of pressure gauges. The valves can be used for clip-on test pressures gauges. The relay nozzles on these positioners are locked in place with locknuts to resist unwanted nozzle movement due to vibration

Input Signal

Standard Ranges: 0.2 to 1.0 bar (3 to 15 psig) or 0.4 to 2.0 bar (6 to 30 psig)

Split Ranges: Typically uses one half of standard range when two control valves are operated by one input signal from a single controller

Optional Ranges: As required within the limits of the bellows

Bellows Pressure Rating

Standard Bellows: 3.4 bar (50 psig)

Optional Bellows: 6.2 bar (90 psig)

Supply Pressure

Maximum: 10.3 bar (150 psig)

Minimum: 2.4 bar (35 psig)

Output Signal

Type: Pneumatic pressure as required by the actuator

Action: Field reversible between direct and reverse (see table 4)

Hysteresis^(1,2)

0.15% of total stroke or instrument pressure span

Resolution^(1,2)

0.2% of instrument pressure span

Repeatability^(1,2)

0.3% of instrument pressure span

Frequency Response^(1,2)

See figure 3

Pressure Connections

Vent: 3/8 NPT

All Others: 1/4 NPT

Pressure Indications

3570C: Tire valves accept standard pressure gauge chucks

3570: See table below

Type of Indication	Number Used	Standard Gauge Range bar (psig)
Positioner input signal gauge	1	0 to 2.1 (0 to 30) or 0 to 4.1 (0 to 60)
Cylinder supply pressure gauge	0	0 to 11.0 (0 to 160)

Static Air Consumption⁽³⁾

0.56 normal m³/hr (20 scfh) with 6.9 bar (100 psig) supply pressure

Operative Ambient Temperature^(1,2)

With Nitrile O-Rings: -34 to 79°C (-30 to 175°F)

With Fluorocarbon O-Rings (Optional):⁽³⁾

-18 to 149°C (0 to 300°F)

Construction Materials**Actuator:**

Part	Material
Base, Cover and Beam	Aluminum, die cast
Bellows	Brass
Bias and Range Spring	Steel, Plated
Relay Body	Zinc, Die Cast
Relay Nozzle(s)	SST
Diaphragm	Nitrile or Fluorocarbon
O-Rings	Nitrile or Fluorocarbon

Options

Fisher SS-52 clip-on chuck (with or without gauge) for 3570C positioners

1. These terms are defined in ANSI/ISA Standard S51.1

2. For actuator with positioner only. Does not apply to other constructions or actuator-valve combination.

3. Normal m³/hr.- normal cubic meters per hour (0°C and 1.01325 bar, absolute); Scfh - standard cubic feet per hour (60°F and 14.7 psia).

Figure 2. Supply Pressure and Thrusts

NOTE:

- 1 MAY BE INCREASED BY 10% FOR ACTUATORS WITHOUT POSITIONERS. EITHER THIS THRUST, OR THE MAXIMUM ALLOWABLE LOADING FOR THE CONTROL DEVICE IS THE LIMITING FACTOR FOR USABLE ACTUATOR FORCE.

Figure 3. Frequency Response

Educational Services

Actuator Configurations

480: Yokeless piston actuator with positioner.

481: Yokeless piston actuator without positioner. Other actuators may be obtained without positioner by adding -1 to the type number.

The above actuators come with standard mounting flange, 105 mm (4.125 inch) maximum rated travel, and threaded piston rod connection with sizes 30 through 60 for mounting on ball valves, louvers, and dampers with brackets.

These actuators may be obtained with the following alternate universal mounting flange constructions:

-15 Added to Type Number: Allows butterfly valve mounting for a standard actuator with 105 mm (4.125 inch) maximum travel and threaded piston rod connection, and comes in sizes 30 through 60.

-16 Added to Type Number: Provides 206 mm (8.125 inch) maximum travel and threaded piston rod connection, and comes in sizes 40 through 60.

Table 4. Action Under Normal Operating Conditions

ACTUATOR DESCRIPTION		DESIRED PISTON MOTION	
		Down	Up
With Positioner	Direct-acting	Increasing input signal pressure to bellows ⁽¹⁾	Decreasing input signal pressure to bellows ⁽¹⁾
	Reverse-acting	Decreasing input signal pressure to bellows ⁽¹⁾	Increasing input signal pressure to bellows ⁽¹⁾
Without positioner		Supply pressure loaded on top of piston, exhausted from bottom	Supply pressure loaded on bottom of piston, exhausted from top

1. Supply pressure is routed through relays to piston.

Installation

WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Personal injury or equipment damage caused by sudden release of pressure may result if the valve assembly is installed where service conditions could exceed the limits given in table 1 or 3 or on the appropriate nameplates. To avoid such injury or damage, provide a relief valve for overpressure protection as required by accepted industry or local, state, and Federal codes and good engineering practices.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

Inspect this equipment on arrival to note any damage which may have occurred in transit. If the actuator is attached to a valve body when received, install the valve in the pipeline with flow in the direction of the arrow on the valve body. (Some valve types, notably various butterfly valves, can be installed with flow in either direction and are unmarked as to proper flow direction.)

A three-valve bypass around the main valve is recommended to permit continuous operation during periodic maintenance or inspection of the main valve.

Figure 4. Operation of Actuator with Positioner

When 480 Series actuators are supplied to operate dampers, louvers, or similar equipment, a suitable mounting plate should be provided, and the piston rod of the actuator connected to the operating arm of the damper, etc., with appropriate linkage.

Figure 5. Cylinder Diameter and Bolt Center Location, All Actuators (refer to table 5)

Table 5. Cylinder Diameter and Bolt Center Location, All Actuators

ACTUATOR SIZE	C		H, DEGREE OF ARC	
	mm	Inch	Standard Flange	Universal Mounting Flange
30	171	6.75	0	45
40	206	8.12	45	45
60	267	10.50	22.5	45

Figure 6. Operation of Actuator with Snubber

Principle of Operation

Actuator

These actuators react to a pressure unbalance that is created by loading supply pressure on one side of the piston and unloading the opposite side. Some type of switching device is required to shift the supply pressure from one side of the piston to the other. For most actuators in the 480 Series, this device is a 3570 positioner. However, a separate loading device must be provided for actuators without positioners.

For actuators with positioners (figure 4), the pneumatic output signal from a controller or instrument is piped to the positioner bellows. As long as the bellows receives a constant input signal pressure, the beam remains motionless and allows supply pressure to bleed through both relay nozzles so that a constant pressure is maintained between the nozzle and the fixed orifice. The relays are in equilibrium with their inlet and exhaust valves closed.

Assume that a downward piston motion is required and the bellows receives a corresponding change in input signal pressure. This causes the beam to pivot so that it covers the nozzle on relay A. (Beam movement is accomplished either by increasing the input signal pressure on a direct-acting positioner to expand the bellows, or by decreasing the input signal pressure on a reverse-acting positioner to contract the bellows.)

The nozzle pressure in relay A increases due to the restriction created by the beam over the nozzle. Through relay action, the air pressure to the top of the piston is increased. At the same time, relay B reacts to the change in beam position to decrease the pressure to the underside of the piston. Due to the resulting unbalanced forces acting on the piston, it moves down, changing the valve plug position.

Piston movement is fed back to the beam by means of a range spring which is connected to the beam and to the piston rod extension, applying a force to the beam opposite to that caused by the expanding or contracting bellows. This feedback arrangement prevents overcorrection and ensures a definite position of the piston and valve plug for a given instrument signal.

If upward piston motion is required, the beam pivots over the nozzle on relay B. The result is relay, piston, and feedback action opposite that for downward piston motion.

Reversal of positioner action is accomplished simply by removing four screws, inverting the bellows, and installing two bellows posts for support if the change is from direct to reverse action. Bellows posts are stored in the positioner case and are not used if the change is from reverse to direct.

Actuator with Snubber

As the actuator piston strokes, the snubber piston moves inside an oil-filled cylinder, forcing oil from one side of the piston to the other through two check valves (see figure 6). The resistance to flow created by the settings of the check valves and the shock absorbing quality of the oil combine to damp out any tendency of the valve plug to jump. The plug of each check valve is held off its seat by the positioning of the adjusting screws. Thus, with the adjusting screws backed off all the way, maximum damping will be obtained.

Pressure Connections

480

The 3570 positioner, an integral part of 480 actuator units, is factory-assembled to the actuator. Two connections, "Supply" and "Instrument", remain to be made after valve installation. Both are 1/4 NPT holes in the positioner and are labelled. Minimum supply pressure is 2.4 bar (35 psig), but for optimum performance, supply pressure should be held as near as possible to the 10.3 bar (150 psig) maximum. Supply pressure air or gas should be clean and dry, as well as non-corrosive. Use of a Fisher 252 filter is recommended.

The positioner case should always be vented to prevent pressure buildup. If the valve is installed with the actuator below the pipeline, provide a new vent location in the lowest part of the case by removing the cadmium-plated pipe plug from the case and screwing it into the standard vent location. This also serves as a drain hole to prevent accumulation of condensate.

481

The 481 actuator also requires 1/4 NPT external supply pressure piping. The 481 has only a pressure tap cover on top of the cylinder. Supply air pressure must be connected to it, and also to the lower cylinder connection located near the cylinder/cylinder flange joint. An external four-way valve or other switching device must be provided between the main supply pressure line and these two actuator pressure connections.

Adjustments

All three adjustments on the 480 actuator are on the 3570 positioner. For further information on the positioner, such as Adjustments, Maintenance, Reversing, and Relay Operation, refer to the Fisher 3570 instruction manual, [D200137X012](#).

The 481 actuator requires no adjustments.

Actuator Maintenance

WARNING

Avoid personal injury from sudden release of process pressure. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

It is necessary for efficient and proper operation of the actuator that all parts be free from dirt, abrasives, and foreign material. Upon assembly at the factor, all synthetic rubber O-rings have been coated with water-resistant lithium grease. It is recommended that this lubricant be used on all O-rings, especially those on moving parts or in contact with moving parts, whenever the actuator is dismantled.

Disassembly

Refer to figures 7 and 8.

References to “positioner” can be ignored if a 481 actuator is involved.

1. Bypass the valve body or shut off the pressure in the pipeline.

CAUTION

The adjustable linkage between the actuator and the main valve should not be disconnected when the valve is open with fluid flowing. (Dampers or louvers should be in safe, stable positions prior to disconnection.)

2. Shut off all pressure to the actuator. Remove all tubing lines (cylinder, instrument, and supply) from the actuator.
3. Remove the positioner cover after loosening the four cover screws on the underside of the positioner base.
4. Disengage the range spring by unscrewing the spring retainer from the piston rod extension.
5. Loosen the two cap screws that hold the positioner to the cylinder. When removing the positioner, do not lose the small O-ring that is used in the passage from the positioner to the top of the cylinder.
6. Next remove the clevis bolt from the adjustable linkage. Remove the bottom snap ring (key 26) and unscrew the clevis and the boot locknut from the actuator piston rod.
7. Remove the nuts that hold the cylinder to the mounting flange and lift off the cylinder.
8. Remove the stud bolts (key 123) that hold the cylinder to the cylinder flange. Two slots, 180 degrees apart, are located at the lower edge of the cylinder. Insert a screwdriver in these slots and pry the cylinder loose. The piston and piston rod will come out with the cylinder. the piston can then be removed by pulling it out the open end of the cylinder.
9. Unscrew both seal bushings (keys 7 and 8).
10. Inspect all parts for excessive wear and defects. Replace all worn O-rings. Lubricate as mentioned above.
11. To reassemble, reverse the above procedure.

Note

When reassembling the actuator after the piston rod extension (key 5) has been removed from the piston rod (key 4), clean the threads of the piston rod thoroughly and apply a thread locking adhesive (medium strength) to the threads. Tighten the piston rod extension securely to a torque of 203 N•m (150 lbf•ft). This torque is approximately equal to the torque that would be developed by placing a force of 150 pounds on the end of a one-foot wrench, 75 pounds on the end of a two-foot wrench, etc.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, refer to the serial number found on the actuator nameplate (key 22).

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

1.1 Scope of the Manual

This instruction manual provides installation, operation and maintenance information for the Fisher 525 Manual Pneumatic Override.

WARNING

Do not install, operate or maintain a 525 Manual Pneumatic Override without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury and property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

1.2 Description

The Fisher 525 Manual Pneumatic Override is a manual switching valve. The 525 MPO is installed between a positioner/controller and a pneumatic actuator, allowing an operator to switch between instrument control and manual control of a pneumatically actuated valve. The 525 MPO includes Lockout/Tagout features to lock the 525 MPO and valve in a desired position and prevent accidental or unauthorized operation.

Figure 1. Fisher 525 Manual Pneumatic Override

1.3 Specifications

Specifications for the 525 MPO are listed in Table 1.

Table 1. Specifications

Available Configurations	Supply and Output Connections
Single or Double-Acting	1/4 NPT internal
Supply Pressure ⁽¹⁾	Ambient Operating Temperature Limits ⁽¹⁾
Maximum: 10.3 bar / 150 psig or maximum pressure rating of the actuator, whichever is lower	-40 to +71°C / -40 to +160°F
Supply Pressure Medium	Hazardous Area Classification
Air or Natural Gas Supply medium must be clean, dry and non-corrosive Per ISA Standard 7.0.01 A maximum 40 micrometer particle size in the air system is acceptable. Further filtration down to 5 micrometer particle size is recommended. Lubricant content is not to exceed 1 ppm weight (w/w) or volume (v/v) basis. Condensation in the air supply should be minimized. Pressure Dew Point: At least 10°C less than the lowest ambient temperature expected Per ISO 8573-1 Maximum particle density size: Class 7 Oil content: Class 3 Pressure Dew Point: Class 3 or at least 10°C less than the lowest ambient temperature expected	Complies with the requirements of ATEX Group II Category 2 Gas and Dust  Ex h IIC Tx Gb Ex h IIIC Tx Db Maximum surface temperature (Tx) depends on operating condition Gas: T6 Dust: T71 Refer to Figure 15 for location of ATEX marking.
	Approximate Weight
	4.7 kg / 10.4 lbs
1. The pressure/temperature limits in this document and any applicable standard or code limitation should not be exceeded.

Section 2: Installation

⚠ WARNING

To avoid personal injury or property damage resulting from the sudden release of pressure:

- Always wear protective clothing, gloves and eyewear when performing any installation operations.
- Personal injury or system damage may result when service conditions exceed controller or other equipment ratings. Exceeding the pressure specifications in Table 1 may cause leakage, parts damage or personal injury due to bursting of pressure-containing parts or explosion of accumulated gas.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTICE

Do not use sealing tape on pneumatic connections. This instrument contains small passages that may become obstructed by detached sealing tape. Thread sealant paste should be used to seal and lubricate pneumatic threaded connections.

2.1 Field Mounting

525 MPO specified for mounting on a valve actuator is mounted at the factory. If the controller is ordered separately for field installation, mount the controller according to the following instructions.

Figure 2. 525 MPO Mounting Dimensions

For installation orientation, ensure that sufficient clearance is provided for proper operation and that the vent port remains unobstructed. Refer to Figure 3.

Figure 3. 525 MPO Mounting Space

To ensure proper operation, the mode indicator label/handles located on the top view of the 525 MPO must always remain unobstructed and clearly visible during operation. Operators are required to maintain a forward-facing orientation toward the label/handles throughout the entire operation process.

2.2 Pressure Connections

⚠ WARNING

To avoid personal injury or property damage resulting from the sudden release of pressure, do not install any system component where service conditions could exceed the limits given in this manual. Use pressure-relieving devices as required by government or accepted industry codes and good engineering practices.

NOTICE

Do not use sealing tape on pneumatic connections. This instrument contains small passages that may become obstructed by detached sealing tape. Thread sealant paste should be used to seal and lubricate pneumatic threaded connections.

All pressure connections on the 525 MPO are 1/4 NPT internal. Use 10 mm / 3/8-in. pipe or tubing for supply, input and output piping. The pressure connection locations are shown in Figures 4 and 5.

Figure 4. Single-Acting Pressure Connection**Figure 5. Double-Acting Pressure Connection**

2.3 Supply Pressure

⚠ WARNING

Severe personal injury or property damage may occur from an uncontrolled process if the instrument supply medium is not clean, dry, oil-free and non-corrosive. A regularly maintained air filter removing particles larger than 40 micrometers in diameter will suffice in most applications. Further filtration down to 5 micrometer particle size is recommended. If you are unsure of your filtration needs or use a hazardous gas, check with an [Emerson sales office](#) or industry instrument supply medium quality standard.

Supply pressure must be filtered, clean, dry and non-corrosive gas. It must meet the requirements of ISA Standard 7.0.01 or ISO 8573-1. A maximum 40 micrometer particle size in the air system is acceptable. Further filtration down to 5 micrometer particle size is recommended. Lubricant content is not to exceed 1 ppm weight (w/w) or volume (v/v) basis. Condensation in the supply medium should be minimized.

Use a suitable supply pressure regulator to reduce the supply pressure source to the normal operating supply pressure shown in Table 1.

WARNING

To avoid personal injury or property damage resulting from the sudden release of process pressure, use a pressure regulator system when operating 525 MPO from a high-pressure source. Ensure that supply pressure does not exceed the maximum pressure rating of the 525 MPO, actuator or any instruments.

2.4 Vent Port

WARNING

Personal injury or property damage could result from fire or explosion of accumulated gas or from contact with hazardous gas. The controller will exhaust pressure when operating it. If a flammable or hazardous gas is used as the supply pressure medium, adequate ventilation and necessary safety measures should be used to prevent the accumulation of flammable or hazardous gas.

Vent to the atmosphere is through VENT port in the side of the unit. Keep the VENT port free of any obstructions or foreign materials that might clog them.

2.5 Typical Application

WARNING

Avoid personal injury and property damage caused by supply pressure exceeding pressure rating of 525 MPO or attached other instruments.

Refer to Figures 6, 7, 8 and 9.

This section provides typical applications with different types of pneumatic actuator.

Figure 6. Single-Acting Actuator with Push-Down-to-Close

Figure 7. Single-Acting Actuator with Push-Down-to-Open

Figure 8. Double-Acting Actuator with Push-Down-to-Close

Figure 9. Double-Acting Actuator with Push-Down-to-Open

Table 2 illustrates the port cross-connections corresponding to each operational mode of the 525.

Table 2. Double-Acting Configuration⁽¹⁾

525 Modes	Connected Ports	Isolated Ports
Automatic	P1 ↔ C1, P2 ↔ C2	Supply, Vent
Manual-Lock	None	All ports isolated
Manual-Open	C1 ↔ Vent, C2 ↔ Supply	P1, P2
Manual-Close	C1 ↔ Supply, C2 ↔ Vent	P1, P2

1. Single-acting configuration will plug C1 and P1 or C2 and P2 ports, see Figures 6 and 7.

Section 3: Operation

⚠ WARNING

Avoid personal injury and property damage caused by supply pressure exceeding pressure rating of the 525 MPO or other attached instruments or equipment.

3.1 Principle of Operation

Figure 10. 525 MPO Modes

Figure 11. 525 MPO Construction

Auto Mode to Manual Modes Operation

1. AUTO mode is limited by a safety button to prevent accidental mode changes.
2. Rotate the clip clockwise to disengage the limit position, press the safety button, rotate the Auto/Manual handle to MANUAL (M) position, the 525 MPO will be operated to the MANUAL LOCK mode.

NOTE

Pressure will exhaust from vent port when changing modes.

NOTE

Slow changes in valve travel may occur if the 525 MPO is left in manual-lock mode for extended periods of time.

3. Rotate the Position handle to MANUAL OPEN (O) or CLOSE (C) position, the 525 MPO will override any control instruments to position valve open or close.

Figure 12. Auto Mode to Manual Modes Operation

Manual Modes to Auto Mode Operation

1. When the 525 MPO is in MANUAL CLOSE (C) or OPEN (O) mode, rotate the position handle, return to MANUAL LOCK (L) mode.

NOTE

Slow changes in valve travel may occur if the 525 MPO is left in manual-lock mode for extended periods of time.

2. Press the safety button, rotate the Auto/Manual handle, return to AUTO mode, rotate the clip counterclockwise to re-engage it to the limit position.
-

Figure 13. Manual Modes to Auto Mode Operation

The 525 MPO includes features to lock the Manual Pneumatic Override in a desired position and prevent accidental or unauthorized operation. Proper selection of lockout padlock is essential to prevent accidental movement of the Type 525 MPO handles.

Figure 14. Lockout/Tagout Feature

Section 4: Maintenance

There are no repairable or replaceable parts on the 525 MPO. Contact your [Emerson sales office](#) if a replacement 525 MPO is needed, always mention the controller serial number. The serial number can be found on the nameplate.

Introduction

Scope of Manual

This instruction manual provides information on installation, maintenance, and parts ordering for the Fisher 585C piston actuators. Refer to separate instruction manuals for information about other equipment and accessories used with these actuators.

Information for the 585CLS long stroke actuator can be found in the Fisher 585CLS Instruction Manual ([D103793X012](#)).

Do not install, operate, or maintain a 585C Series actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

585C pneumatic piston actuators (figure 1) provide accurate throttling or on-off control of sliding-stem valves. The 585C actuator uses a double-acting cylinder, which requires air pressure for operation.

Size 25 and 50 actuators are available as a springless construction or with a bias spring. Depending on configuration, the bias spring will retract or extend the piston rod upon loss of cylinder air pressure. Size 60 through 130 actuators are available as springless constructions only.

585C actuators are typically supplied with a DVC6200 digital valve controller, or a 3600 P/P or I/P analog positioner. The 585C actuator is available with a top-mounted or side-mounted manual handwheel, depending on actuator size.

Specifications

Specifications for the 585C piston actuators are given in table 1. Some individual actuators come from the factory with specifications stamped on a nameplate attached to the yoke.

Table 1. 585C Specifications (Sizes 25-130)

Operating Pressure⁽¹⁾

Sizes 25-50

Maximum Allowable: 10.3 bar (150 psig)

Minimum Recommended: 1.4 bar (20 psig)

Sizes 60-130

Maximum Allowable: See table 8

Minimum Recommended: 2.4 bar (35 psig)

Travel

See table 2

Thrust Capabilities

See tables 4 through 8

Stroking Speeds

Varies with actuator size, actuator spring, travel, and supply pressure. If stroking speed is critical, consult your [Emerson sales office](#)

Piston Area

See table 2

Cylinder Volumetric Displacement

See table 2

Operative Temperature Limits⁽¹⁾

For All Sizes

Standard Construction

(Nitrile O-Rings): -40 to 80°C (-40 to 175°F)

Optional Construction

(Fluorocarbon O-Rings): -18 to 149°C (0 to 300°F)

For Sizes 60-130

Low Ambient Temperature option:

Fluorosilicone O-Rings: -60 to 80°C (-76 to 175°F)

Yoke Boss and Valve Stem Diameters

See table 3

Pressure Connections

Size 25-60

■ 1/4 NPT internal (standard), or ■ 3/8 NPT internal (optional)

Sizes 68-130

■ 1/2 NPT internal (standard)

Instrument Mounting

Universal NAMUR mounting

Construction Materials

Part	Material
Yoke	Ductile Iron
Piston	Aluminum
Cylinder	Aluminum
Bolting and Fasteners	Steel NCF (std)
	Stainless Steel (std and low ambient)
Springs (sizes 25 and 50 only)	Alloy Steel
O-Rings	Nitrile (std), Fluorocarbon, Fluorosilicone
Actuator Stem	Chrome-plated Steel
Stem Connection	Stainless Steel
Travel Indicator Scale	Stainless Steel
Paint	Polyester Powder
Cylinder Seal Bushings (sizes 60-130 only)	Brass
Stem Connector (sizes 60-130)	Zinc-plated steel (std)
	Stainless Steel (std and low ambient)

Approximate Weights

(less positioner and handwheel)

Size 25

2-1/8 inch yoke boss, 7 kg (16 pounds)

2-13/16 inch yoke boss, 8 kg (17 pounds)

Size 50

2-13/16 inch yoke boss, 20 kg (45 pounds)

3-9/16 inch yoke boss, 22 kg (48 pounds)

Size 60: 31 kg (68 pounds)

Size 68: 54 kg (120 pounds)

Size 80: 102 kg (225 pounds)

Size 100: 113 kg (250 pounds)

Size 130: 188 kg (415 pounds)

Options

Sizes 25 and 50

■ Top-mounted handwheel, see figures 6, 8, and 9 and table 9

■ Cylinder bypass valve ■ Limit switches ■ Fisher 4200 position transmitter

Sizes 60-130

■ Integral side-mounted handwheel, (figure 10)

Sizes 25-130

■ FIELDVUE™ mounting options

■ Fisher 377 trip valve system to fail actuator

■ up or ■ down or ■ lock in last position

■ TopWorx™ DXP M21GNEB electrical valve stem position switch

■ Micro-Switch limit switches

1. The pressure/temperature limits in this manual and any applicable standard or code limitation for valve should not be exceeded.

X—Indicates where the listed supply pressure will exceed the maximum thrust allowable. 1. The maximum design pressure for size 25 through 100 actuators is 10.3 bar (150 psig). The size 68 and 130 actuators are limited to 9.7 and 7.8 bar (140 and 113 psig) respectively. 2. The size 25 and 50 data is for the construction without a bias spring. 3. Minimum operating pressure for sizes 60-130 actuators is 2.4 bar (35 psig). 4. The size 68 actuator with a handwheel is limited to 40000 Newtons (9000 lb) thrust.												

Principle of Operation

The 585C piston actuator (figures 2 and 3) uses a piston that moves inside the actuator cylinder. An O-ring (see figure 3) provides a seal between the piston and the cylinder.

From an equilibrium state, the actuator reacts to a force unbalance that is created by increasing supply pressure on one side of the piston, and decreasing it on the other. This moves the piston up or down, and results in a repositioning of the valve plug.

Actuator with Handwheel (figures 2 and 6)

The handwheel version can be used to open or close the valve manually (either during normal operation or in an emergency), to position the valve at any point in the stroke, or to act as a travel stop.

Size 25 and 50 actuators use an integral top-mounted handwheel. See figure 6.

Size 60 to 130 actuators use a side-mounted handwheel, and come with a spring-loaded ball detent which prevents vibration from changing the handwheel setting. Handwheels for most types are either 203 mm (8 inches) in diameter with beveled gears or 432 mm (17 inches) in diameter with worm gears.

Handwheel Specifications

2. 8 inch maximum travel construction.

Figure 2. Fisher 585C Piston Actuator with Handwheel

E0410

Figure 3. Fisher 585C Piston Actuator with Spring Return

W7447-1

Actuator with Spring Return (figure 3)

585C size 25 and 50 actuators are available with bias springs in two configurations. The 585C actuator, with the bias spring under the piston, fully retracts the actuator stem upon loss of cylinder pressure. The 585C actuator, with the bias spring on top of the piston, fully extends the actuator stem upon loss of cylinder pressure. No additional parts are required to convert from one actuator type to the other.

For more detailed information on the 3610 positioner and DVC6200 digital valve controllers, refer to the Principle of Operation section in the 3610J Instruction Manual ([D200149X012](#)) and [DVC6200](#) instruction manuals.

Installation

⚠ WARNING

To avoid personal injury or property damage caused by cylinder fracture as a result of piston impact, install the stem connector securely before supplying pressure to the positioner. Use only a regulator-controlled air supply to move the actuator piston so that you can install the stem connector. Do not use the positioner to move the actuator piston before installing the stem connector.

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

To avoid personal injury or property damage caused by bursting of pressure-retaining parts, be certain the cylinder pressure or other pressure ratings do not exceed the limits listed in table 1. Use pressure-limiting or pressure-relieving devices to prevent cylinder pressure or other pressure ratings from exceeding these limits.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance sections in this instruction manual.

When an actuator and valve are shipped together as a control valve assembly, the actuator is normally mounted on the valve. Follow the valve instructions when installing the control valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the Actuator Mounting procedures in this instruction manual corresponding to your actuator size. For information on mounting valve positioners, refer to the 3610J Instruction Manual (D200149X012) or DVC6200 instruction manuals for details.

If a 585C actuator is being installed without a positioner, the cylinder loading pressures should be supplied through a 4-way solenoid valve or a switching valve. The bottom side of the piston is pressured through the bottom side of the mounting flange on the actuator yoke (key 6, figures 5 and 7) for sizes 25 and 50 or the connection at the lower side of the cylinder (key 1, figure 10 to 15) for sizes 60 to 130. The top side of the piston is pressured through the connection in the cylinder cover (key 1 for figures 5, 7; and 10 to 15).

The supply pressure medium should be clean, dry filtered air. If the supply source is capable of exceeding the maximum actuator operating pressure or positioner supply pressure, appropriate steps must be taken during installation to protect the positioner and all connected equipment against overpressure.

⚠ WARNING

Dropping the actuator and any attached accessories and/or valve may cause personal injury and/or equipment damage. For all mounting procedures use an adequately sized chain, sling, hoist, or crane to handle the actuator and any attached accessories and/or valve. Use caution during lifting and handling to prevent slippage, swinging, faulty equipment connections, or sudden shock loads.

NOTICE

To avoid damage to actuator parts and difficult operation of actuator handwheels, open the bypass valve before using a handwheel.

If manual operation is required, the actuator should be equipped with a manual handwheel. To manually move the piston rod with the handwheel, first open the bypass needle valve (key 66 for sizes 25 and 50, figure 9; key 92 for sizes 60 to 130, figure 16), place the handwheel pointer in the neutral position, and insert the locking pin in the sleeve assembly (for size 60-130). Then turn the handwheel in the selected direction as indicated on the wheel.

The control valve should be located where it will be accessible for servicing. Room should be left above and below the control valve to permit removal of the actuator and valve plug.

Bypass Assembly

The bypass is furnished as shown in figures 6, 8, 9, and 16 only when a handwheel actuator is specified. The bypass allows the pressure to equalize on either side of the piston, so that the manual actuator can be used to position the valve.

Flow through the bypass tubing is controlled by an angle needle valve (key 66 for figures 6, 8, and 9; and key 92 for figure 16), which is operated manually. This valve should be closed when air pressure is being used to operate the valve.

Three-Way Valve Applications Note

⚠ WARNING

To avoid loss of control of process fluid and subsequent personal injury or property damage caused by bursting of pressure-retaining parts, be sure the cylinder pressure does not exceed 80 psig in high cycle-rate, fast stroking speed, three-way valve applications.

In three-way valve applications where the actuator fully strokes at a frequency of once per minute or faster, and the stroking speed is rapid (less than 0.5 seconds per stroke), there is a possibility that the stem can fracture at the plug if the actuator cylinder pressure is greater than 80 psig. This can cause loss of control of process fluid and further damage to the actuator. Consideration should be given to the use of high-strength, fatigue-resistant stem materials in these applications.

Actuator Mounting

Size 25 and 50 Actuator Mounting

The following procedure describes how to mount a 585C actuator size 25 and 50 on a push-down-to-close valve so that the piston stem to valve plug stem connection allows full travel and proper shutoff. Key numbers referenced in the following steps are shown in figures 5 through 9.

1. If not already removed, remove the stem connector (key 12) by loosening the cap screws (key 14).
2. Thread the stem connector nuts (keys 13 and 15) onto the valve stem, and run the nuts to the bottom of the valve stem threads.
3. Push the valve plug stem until the valve plug is closed for push-down-to-close valve plug action.
4. Place the actuator on the bonnet of the valve and secure the actuator tightly to the bonnet with the yoke locknut.

NOTICE

In the following procedure, do not rotate the valve plug while it is seated since this may cause damage to the seating surface and thereby allow excessive leakage. Also, during adjustment, use tools carefully to avoid damaging the valve plug stem. A damaged valve plug stem could cut the packing and allow leakage.

Note

When using an actuator with handwheel in the following step to stroke the valve plug, be sure the bypass valve (key 66, figure 6, 8, or 9) is open. Rotating the handwheel (key 47, figure 6, 8, or 9) clockwise extends the actuator stem (key 10); rotating the handwheel counterclockwise retracts the actuator stem.

5. Perform one of the following procedures (a or b as appropriate):
 - a. For a 585C actuator with spring retraction upon loss of cylinder pressure (figures 5 and 6) on a push-down-to-close valve, manually move the valve plug to the seated position. Rotate the handwheel or apply pressure to the pressure connection in the cylinder (key 1) until the piston (key 3) and actuator stem (key 10) move down the specified travel. Run the stem connector nut (key 13) up on the valve stem until it contacts the actuator stem. Be sure the flats on the actuator stem are perpendicular to the scale indicator web on the yoke (key 6). Adjust the stem connector nut as necessary, so that the flats on the nut and the actuator stem are parallel. Clamp the actuator stem and stem connector nut together with the stem connector (key 12) and the two cap screws and hex nuts (keys 14 and 23). Run the hex nut (key 15) up the valve stem and tighten against the stem connector nut (key 13).
 - b. For a 585C actuator with spring extension upon loss of cylinder pressure (figures 7 and 8) with push-down-to-close valve, manually move the valve plug to the seated position. Run the stem connector nut (key 13) up the valve stem until it contacts the actuator stem (key 10). Rotate the handwheel or apply pressure to the pressure connection in the yoke (key 6) to move the actuator stem (key 10) approximately 1/4 inch away from the stem connector nut. Rotate the stem connector nut so that it moves up the valve stem two full turns. Manually move the valve plug so that the stem connector nut again contacts the actuator stem. Be sure the flats on the actuator stem are perpendicular to the scale indicator web on the yoke (key 6). Adjust the stem connector nut, as necessary, so that the flats on the nut and the actuator stem are parallel. Clamp the actuator stem and stem connector nut together with the stem connector (key 12) and the two cap screws and hex nuts (keys 14 and 23). Run the hex nut (key 15) up the valve stem and tighten it against the stem connector nut (key 13).
6. Cycle the actuator several times to check for proper operation.

Note

In the following step, make sure the correct travel indicator scale (key 19) is used per the Parts List for the desired travel.

7. If necessary, remove the travel indicator scale screws (key 18) and reposition the travel indicator scale (key 19) so that the scale arrow points in the same direction as the valve plug moves when opening. Close the valve. Adjust the scale up or down so that the stem connector (key 12) indicator lines up with the closed mark on the scale. Secure the scale with the scale screws.

Size 60-130 Actuator Mounting

The following procedure describes how to mount a 585C size 60 to 130 actuator on a push-down-to-close valve so that the piston stem to valve plug stem connection allows full travel and proper shutoff. Key numbers referenced in the following steps are shown in figures 10 through 15.

If an actuator is purchased separately for field installation on a control valve, mount it on the valve and secure it in place with the yoke locknut for size 60 and 68 or with eight bolts on actuator sizes 80, 100, and 130 which use a 127 mm (5-inch) yoke boss.

The stem connector should then be set up to clamp the actuator stem and valve plug stem together to provide the proper valve travel. This procedure is outlined in the Stem Connector Assembly procedures of this instruction manual.

Stem Connector Assembly (Size 60-130)

NOTICE

To avoid damaging the seating surfaces, do not rotate the valve plug while it is seated. Also avoid damage to the valve plug stem by careful use of tools during travel adjustment.

⚠ WARNING

- To avoid personal injury or property damage caused by cylinder fracture as a result of piston impact, install the stem connector securely before supplying pressure to the positioner. Incomplete engagement of valve stem and/or actuator stem in the stem connector can result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than the diameter of that stem. Do not loosen the cap screws when the stem connector has spring or loading pressure force applied to it.
- Install the stem connector securely before a positioner is mounted to the actuator and pressurized, using only a regulator- controlled air supply, *not the positioner*, to move the actuator piston to position the actuator stem.
- To avoid personal injury or property damage, keep hands and tools out of the actuator stem travel path while pressuring the actuator to move the actuator stem in the following steps.

585C Size 60-130 Direct-Acting (Push-Down-to-Close) Valves

1. With the valve assembled and the actuator mounted, make sure the valve plug is in the closed position, and the actuator is at the top of its stroke. Then screw the two stem locknuts (key 15) all the way onto the stem thread and place the travel indicator disk (key 32) (if any) on the stem locknuts.
2. Keeping your hands away from any moving parts, use a regulator-controlled air supply to move the actuator stem (key 10) down from the top of its stroke to the specified valve travel.
3. Using one half of the stem connector (key 12), align the actuator stem and the valve stem with threads from *both* stems mated root-to-crest with the stem connector. Install the other half of the stem connector and tighten the cap screws. With the stem locknuts (key 15), raise the travel indicator disk (key 32) to the stem connector (key 12).
4. Cycle the actuator to check availability of desired total travel and that the valve plug seats before the actuator contacts the lower travel stop. Minor travel adjustments can be made by loosening the stem connector (key 12) slightly, tightening the locknuts (key 15) together, and screwing the valve stem either into or out of the stem connector (key 12) with a wrench on the locknuts (key 15). If the valve stem cannot be turned, as with a bellows seal bonnet, remake the stem connection to achieve the desired travel.
5. Once the total travel is adequate, tighten the stem connector (key 12) securely, lock the stem locknuts (key 15) against the connector, and adjust the indicator scale (key 19) on the yoke to show correct valve plug position.

6. Provide a gauge to measure the pressure to the actuator. Make a final adjustment of the actuator or its positioner to set the starting point of valve travel and to obtain full travel for the given instrument range.

585C Size 60-130 Reverse-Acting (Push-Down-to-Open) Valves

1. Keeping your hands away from moving parts, pressure the actuator, using a regulator-controlled air supply, to move the actuator stem (key 10) to the extreme upward position then reverse loading pressure to lower the actuator stem (key 10) approximately 3 mm (1/8 inch).
2. Pull the valve stem up to seat the valve plug.
3. Using one half of the stem connector (key 12), align the actuator stem and the valve stem with threads from *both* stems mated root-to-crest with the stem connector. Install the other half of the stem connector and tighten the cap screws.
4. If there is a travel indicator disk (key 32), raise it to the stem connector (key 12) and tighten in position with the stem locknuts (key 15). The indicator disk (key 32) should show the valve to be open with the piston (key 3) at the bottom of its stroke. If it does not, loosen two screws (key 18) and shift the travel indicator scale (key 19) to indicate OPEN.
5. Cycle the actuator to check availability of desired total travel and that the valve plug seats before the actuator contacts the upper travel stop. Minor travel adjustments can be made by loosening the stem connector (key 12) slightly, tightening the locknuts (key 15) together, and screwing the valve stem either into or out of the stem connector (key 12) with a wrench on the locknuts. If the valve stem cannot be turned, as with a bellows seal bonnet, remake the stem connection to achieve the desired travel.
6. Once the total travel is adequate, tighten the stem connector (key 12) securely, lock the stem locknuts (key 15) against the connector, and adjust the indicator scale (key 19) on the yoke to show correct valve plug position.
7. Provide a gauge to measure the pressure to the actuator. Make a final adjustment of the actuator or its positioner to set the starting point of valve travel and to obtain full travel for the given instrument range.

585C Handwheels

Handwheel Operation (Sizes 25 and 50)

Key numbers referenced in the following steps are shown in figures 6, 8, and 9 for the 585C actuator.

The handwheel assembly on a 585C actuator may be used as an adjustable travel stop to limit full upward or downward travel of the actuator stem (key 10), or as a manual actuator to fully stroke the valve. When the neutral indicator (key 42) is in the neutral position, travel is not restricted. With clockwise handwheel (key 47) rotation, the operating nut (key 46) is screwed downward, forcing the actuator stem (key 10) down. With counterclockwise rotation, the operating nut is screwed upward against the handwheel stem washer (key 45), pulling the actuator stem up.

Note

When using an actuator with handwheel to stroke the valve plug or position the travel stop, be sure the bypass valve (key 66) is open.

Handwheel Operation (Sizes 60-130)

The 585C handwheel assembly for sizes 60 through 130 actuators (figures 10 and 12) has three main functions:

- To open or close the valve manually or to position the valve at any point in the stroke, regardless of the cylinder pressure. The tapered pin is inserted during manual throttling operation.
- To act as a travel stop to limit full opening or closing of the valve but not both at the same time. As shown in table 11, the tapered pin is left out when the assembly is used as a travel stop.
- To open or close the valve manually in an emergency without the necessity of inserting the tapered pin, as shown in table 11.

Bevel gears are used in sizes 60 and 68 and worm gears in sizes 80 through 130. A spring-loaded ball detent is provided in the handwheel to prevent a change in setting due to vibration. The following table 10 lists pertinent information on these handwheel units.

Table 10. Fisher 585C Size 60 to 130 Handwheel Information

Actuator Size	60-68	80-130
Handwheel Diameter, Inches	8	17
Turns Required for One Inch of Travel	16	10

Table 11. Fisher 585C Size 60 to 130 Handwheel Information with Travel Stop Function and Emergency Operation without Tapered Pin Engaged

Actuator Size	Maximum Travel, Inch	Used as Upper Travel Stop	To Close the Valve without Tapered Pin Engaged	Used as Lower Travel Stop	To Open the Valve without Tapered Pin Engaged
60 and 68	2	Yes		Yes	
	4 and 8			No	
80, 100, and 130	4	Yes		Yes	
	8			Yes but with travel restriction	

Maintenance (Sizes 25 and 50)

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends on the severity of service conditions. This section provides two separate procedures, one on Replacing Handwheel Housing O-Ring or Thrust Bearings, and the other on Replacing Seals, Changing Action, or Changing Bias Spring(s).

Refer to figures 6 and 8.

For an actuator with handwheel, a grease fitting (key 50) is provided on the bearing cover (key 38) for periodic bearing lubrication with lithium grease (key 24).

WARNING

Avoid personal injury from sudden release of process pressure. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.

- Vent the power actuator loading pressure and release all bias spring compression force by slowly unscrewing the cylinder cover bolting in a crisscross pattern.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Replacing Handwheel Housing O-Ring or Thrust Bearings (Sizes 25 and 50)

Perform this procedure if inspecting or replacing the handwheel housing O-ring, handwheel thrust bearings, or any other handwheel parts located above the cylinder (key 1). Inspection or replacement of the cylinder O-ring, handwheel stem, or handwheel stem jam nut (key 57, 56, or 52) are covered in the Replacing Seals, Changing Action, or Changing Bias Spring(s) procedure. Key numbers are referenced in figure 6 for a 585C actuator (spring retracts actuator rod) and in figure 8 for a 585C actuator (spring extends actuator rod).

Note

This procedure may be performed without removing the cylinder, or yoke (key 1 or 6) from the bonnet of the valve.

Disassembly

Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Shut-off all pressure lines and power to the actuator, and release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

WARNING

Refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

1. Shut off the bypass valve (key 66). Remove the cylinder pressure piping and bypass tubing from the bypass tees (key 68) on the cylinder (key 1).
2. Turn the handwheel (key 47) in the appropriate direction so the neutral indicator (key 42) is behind the NEUTRAL position of the neutral indicator plate (key 37).
3. Unscrew and remove the neutral indicator cover (key 35).
4. Remove the handwheel retaining ring, handwheel, and locking key (keys 48, 47, and 65).
5. Loosen the bearing cover set screws (key 51), and unscrew and carefully remove the bearing cover (key 38).
6. Remove the handwheel housing O-ring (key 58) and the top set of thrust bearings (key 39).
7. Since both the handwheel housing (key 36) and the operating nut (key 46) have left-hand threads, unscrew the handwheel housing by turning it clockwise off the operating nut. Carefully remove the detent ball and detent spring (keys 64 and 63), and remove the bottom set of thrust bearings (key 39).

8. Unscrew the handwheel stem cap screw (key 60) while using a 7/8 inch wrench to hold the handwheel stem (key 56). Remove the handwheel stem washer (key 45), and the operating nut (key 46) with attached neutral indicator (key 42).
9. Unscrew the neutral indicator (key 42) counterclockwise if necessary to separate it from the operating nut (key 46).

Reassembly

1. If the neutral indicator (key 42) was removed, coat its threads with thread locking adhesive (medium strength) (key 70) and screw it into the operating nut (key 46). Position the 90-degree elbow of the neutral indicator so that it will not interfere with the neutral indicator cover (key 35) when assembled.
2. If necessary, replace the anti-rotation key (key 40), by pushing the key outward from the cylinder (key 1) then install the replacement key (key 40) into the anti-rotation hole of the cylinder.
3. Lubricate the inside surface of the operating nut (key 46) with lithium grease (key 24). Install the operating nut with the attached neutral indicator, and the handwheel stem washer (key 45), onto the handwheel stem (key 56) and secure with the handwheel stem cap screw (key 60). Tighten the cap screw to 169 N•m (125 lbf•ft).
4. Place the bottom set of thrust bearings (key 39) on top of the cylinder (key 1). Insert the detent spring and ball (keys 63 and 64) into the cylinder.
5. Install the handwheel housing O-ring (key 58) on the handwheel housing (key 36). Since both the handwheel housing and the operating nut (key 46) have left-hand threads, thread the handwheel housing onto the operating nut by turning it counterclockwise over the operating nut until the handwheel housing is snug against the bottom set of thrust bearings (key 39).
6. Install the top set of thrust bearings (key 39) over the handwheel housing (key 36).
7. Carefully slide the bearing cover (key 38) over the handwheel housing (key 36) and thread the bearing cover hand tight onto the cylinder (key 1). Secure by tightening the set screws (key 51) to 18 N•m (13 lbf•ft).
8. Install the locking key, handwheel, and handwheel retaining ring (keys 65, 47, and 48).
9. Screw the neutral indicator cover (key 35) hand tight only onto the handwheel housing (key 36).
10. Install the bypass tubing with attached bypass valve (key 66) into the bypass tees (key 68) in the cylinder (key 1).

Replacing Seals, Changing Action, or Changing Bias Spring(s) (Sizes 25 and 50)

Key numbers are referenced in figures 5 and 6 for a 585C actuator (spring retracts actuator rod) and in figures 7 and 8 for a 585C actuator (spring extends actuator rod).

Disassembly

Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Shut-off all pressure lines and power to the actuator, release all pressure from the actuator, and release all bias spring compression force by slowly unscrewing the cylinder cover bolting in a crisscross pattern. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

WARNING

Refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

For 585C actuators with push-only handwheel, figure 9, be sure the handjack stem is backed out of the cylinder as far as it will go to relieve any extra spring compression.

1. Remove the cylinder pressure piping. With a handwheel construction, perform steps 1. through 2. of the Replacing Handwheel Housing O-Ring or Thrust Bearings procedure.

Note

In the following step, loosen each cylinder-to-yoke cap screw a slight amount in turn in a crisscross pattern to keep the cylinder square with the yoke while relieving spring precompression.

2. While carefully allowing bias spring precompression to be slowly released, remove the cylinder-to-yoke cap screws and cylinder cover (keys 2 and 1).

NOTICE

When performing the following step, set the cylinder on a protective surface to prevent damage to the cylinder surfaces.

3. Remove the cylinder (key 1). Set the cylinder on a protective surface to prevent damage to the cylinder surfaces. With a handwheel construction, inspect the cylinder O-ring (key 57) and replace it if necessary, applying lithium grease (key 24) to the replacement O-ring.
4. Inspect the piston O-ring (key 8) and replace, if necessary. If the only further maintenance to be performed is replacement of the piston O-ring, skip to step 3 of this procedure.

Note

585C actuators may be used with or without the bias springs. In the following procedures, references are made to the bias springs. If the bias springs are not used, disregard references to them when performing the maintenance procedures.

5. Perform one of the following disassembly procedures (a, b, c, d, or e, as appropriate):
 - a. For 585C actuators without handwheel (*If the bias spring is present, it extends the piston rod.*) (figure 7), remove the piston cap screw (key 4), piston (key 3), bias spring(s) (key 16 and/or key 17), and travel stop spacer (key 5).
 - b. For 585C actuators with handwheel (*If the bias spring is present, it extends the piston rod.*) (figure 8), remove the handwheel stem (key 56) with attached piston stud (key 69), piston (key 3), bias spring(s) (key 16 and/or key 17), and travel stop spacer (key 5).
 - c. For 585C actuators without handwheel (*If the bias spring is present, it retracts the piston rod.*) (figure 5), remove the bias spring(s) (key 16 and/or key 17), piston cap screw (key 4), travel stop spacer (key 5) and piston (key 3).
 - d. For 585C actuators with handwheel (*If the bias spring is present, it retracts the piston rod.*) (figure 6), remove the bias spring(s) (key 16 and/or key 17), the handwheel stem (key 56) with attached piston stud (key 69), travel stop spacer (key 5), and piston (key 3).
 - e. For 585C actuators with push-only handwheel (figure 9), remove the cotter pin and slotted nut (keys 73 and 72) and lift off the handwheel. Remove the jam nut (key 52). Remove the cap screws (key 60) and lift off the handwheel housing (key 36). Back the handwheel stem (key 56) out of the housing. Inspect the O-rings (keys 57 and 58). Replace these parts as necessary.
6. If inspection or replacement of the actuator stem O-ring or bearing (key 9 or 11) is necessary, perform steps 1. through 7. Otherwise, skip to step 2, being sure to comply with the note preceding step 2.

7. Loosen the two cap screws in the stem connector (key 14) and remove it. If the actuator is mounted on a valve, separate the actuator stem (key 10) from the valve plug stem. Remove the actuator from the valve.
8. To inspect the actuator stem bearing (key 11), actuator stem O-ring (key 9), or backup ring (key 25, size 50 only) remove the actuator stem (key 10) from the yoke (key 6). Replace these parts if necessary. Apply lithium grease (key 24) to the replacement O-ring or bearing and install it into the yoke.

Assembly

1. Install the actuator stem through the yoke.

Note

Make certain the travel indicator scale (key 19) correctly matches the travel per the Parts List.

2. To achieve the desired construction (either a direct-acting or a reverse-acting 585C actuator), perform one of the following assembly procedures (a, b, or c, as appropriate):
 - a. For 585C actuators (bias spring retracts the piston rod) (figures 5 and 6), center the inner bias spring, if used, (key 17 per table 6 or 7) around the center boss in the yoke (key 6). If used per table 6 or 7, center the outer bias spring (key 16) around the inner bias spring. The outer bias spring should be within the outer boss in the yoke. Put the travel stop spacer and the piston (keys 5 and 3) on the actuator stem. Apply lithium grease (key 24) to the threads of the piston cap screw or piston stud (key 4 or 69). Insert the piston cap screw, or stud plus attached handwheel stem (key 56), through both the piston and travel stop spacer and into the actuator stem. Use a wrench on the flats of the actuator stem to prevent it from turning. Tighten the piston cap screw, or stud plus attached handwheel stem, to 102 N•m (75 lbf•ft) for size 25 actuators or 136 N•m (100 lbf•ft) for size 50 actuators.
 - b. For 585C actuators with push-only handwheel (figure 9), lubricate the O-rings and handjack stem threads with lithium grease. Install the O-ring (key 57) and handjack stem (key 56), turning the screw into the housing as far as possible. Place the O-ring (key 58) over the housing and insert into the cylinder (key 1). Replace the cap screws (key 60) and tighten to 41 N•m (30 lbf•ft) on size 25 actuators or 81 N•m (60 lbf•ft) on size 50 actuators. Replace the jam nut (key 52), handwheel (key 47), and slotted nut and cotter pin (keys 72 and 73).
 - c. For 585C actuators (bias spring extends the piston rod) (figures 7 and 8), put the piston (key 3) on the actuator stem and the travel stop spacer (key 5) on the piston. Apply lithium grease (key 24) to the threads of the piston cap screw or piston stud (key 4 or 69). Insert the piston cap screw, or stud plus attached handwheel stem (key 56), through both the travel stop spacer and piston and into the actuator stem. Use a wrench on the flats of the actuator stem to prevent it from turning. Tighten the piston cap screw, or stud plus attached handwheel stem, to 102 N•m (75 lbf•ft) for size 25 actuators or 136 N•m (100 lbf•ft) for size 50 actuators. Center the inner bias spring, if used, (key 17 per table 4 or 5) around the travel stop spacer. If used per table 4 or 5, center the outer bias spring (key 16) around the inner bias spring. The outer bias spring should be within the outer boss on the piston.
3. Install the piston O-ring (key 8) if it was removed from the piston, and the yoke O-ring (key 7, figure 5 or 7) if it was removed from the yoke (key 6). Apply lithium grease (key 24) to the wall of the cylinder (key 1) and carefully slide the cylinder over the piston O-ring. Be sure the cylinder pressure connection is aligned with the yoke pressure connection. Square the cylinder in place over the yoke O-ring.
4. Line up the cylinder holes with the yoke holes making sure for a handwheel construction that the anti-rotation groove in the handwheel stem (key 56) is aligned with the hole in the cylinder for the anti-rotation key (key 40).

Note

When placing the cylinder on the yoke and tightening the cylinder-to-yoke bolts, be sure to keep the cylinder square and aligned with the top of the yoke.

5. Lubricate the cylinder-to-yoke bolts (key 2) with lithium grease (key 24). In a criss cross pattern, alternately tighten each cylinder-to-yoke bolt a slight amount so that the cylinder stays square with the yoke. When all cylinder surfaces are in contact with the yoke, tighten each cylinder-to-yoke bolt to 70 N•m (55 lbf•ft) for a size 25 or 95 N•m (70 lbf•ft) for a size 50.
6. With a handwheel construction, perform steps 2 through 10 of the Replacing Handwheel Housing O-ring or Thrust Bearings procedure.
7. If the actuator will be mounted on a valve, perform the appropriate actuator mounting procedure. Otherwise, place the stem connector nut (key 13), stem connector (key 12), two cap screws (key 14), two hex nuts (key 23) and hex nut (key 15) in a parts bag and attach the bag to the actuator yoke.

Maintenance (Sizes 60-130)

WARNING

To avoid personal injury or property damage caused by cylinder fracture as a result of piston impact, install the stem connector securely before supplying pressure to the positioner. Use only a regulator-controlled air supply to move the actuator piston so that you can install the stem connector. Do not use the positioner to move the actuator piston before installing the stem connector.

WARNING

Avoid personal injury from sudden release of process pressure or uncontrolled process fluid. Before starting disassembly:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Key numbers indicated refer to figures 10 through 15.

Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Shut-off all pressure lines and power to the actuator, and release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

1. If positioner is not used, go to step 5. If positioner is used, shut off all pressure lines to the positioner then remove all tubing lines (cylinder, instrument and supply) from the positioner.

NOTICE

Do not use wrenches or other tools directly on the valve stem. Damage to the stem surface could result in subsequent damage to the valve packing.

2. Remove the stem connector (key 12) and the piston rod boot (key 29) used to protect the lower end of the actuator stem.
3. Remove the socket head cap screws that hold the cylinder (key 1) to the yoke (key 6).

NOTICE

Exercise care in the following step to prevent damage to the cylinder wall during removal of the cylinder from the yoke.

4. Insert a screwdriver in the two slots on the lower edge of the cylinder casting and pry the cylinder loose from the yoke. Remove the cylinder, being careful not to mar the cylinder wall.
5. The piston (key 3) and actuator stem (key 10) will come out with the cylinder. The piston can then be removed by forcing it out the open end of the cylinder.
6. Unscrew the seal bushing (key 110 or 26), in the upper end of the yoke (key 6).
7. With the unit disassembled, inspect all parts for excessive wear. Replace all worn O-rings. Lubricate with lithium grease for standard service and Krytox[®] GPL 202 for low ambient temperature service (key 24) as indicated on the assembly drawings. Apply sealant (key 70) as indicated on the assembly drawings.
8. When reassembling the actuator after the piston nut (key 4) has been removed from the actuator stem (key 10), clean the threads of the piston nut thoroughly and apply thread sealant to the threads. Tighten the piston nut securely to a torque of 237 N•m (175 lbf•ft) for size 60 actuators, 1290 N•m (950 lbf•ft) for size 68, 80, and 100 actuators, or 2070 N•m (1530 lbf•ft) for size 130 actuators.

Side-Mounted Handwheel Maintenance (Sizes 60-130)

Refer to figure 10, 11, and 12.

1. The handwheel parts should be fully lubricated periodically per figure 10, 11, 12, and 13. Lack of lubrication might cause handwheel to malfunction or reduction of output thrust. A grease fitting (key 140) is provided on sizes 80, 100, and 130. On sizes 60 and 68, remove the handwheel (key 118) and the bevel pinion (key 116) and pack the gear case with lithium grease. Loosen the set screw (key 139) before attempting to remove the pinion and extension.
2. If it is necessary to change the valve plug action from push-down-to-close to push-down-to-open or vice versa, change the handwheel arrangement so that the arrow indicates the correct rotation required to open the valve.
 - a. For sizes 60 and 68, remove the handwheel, invert and replace it. On sizes 60 and 68 (figure 10), remove and replace the spring-loaded ball assembly (key 123) in the opposite side.
 - b. For sizes 80-100, remove the handwheel assembly and install in the opposite end of the gear case by unscrewing the back and front worm retainers (keys 135 and 136, not shown) and turn the handwheel to disengage the bevel pinion (key 116).

Disassembly of Handwheel Constructions (Sizes 60 and 68)

⚠ WARNING

Refer to the WARNING at the beginning of the Maintenance section (Sizes 60-130) in this instruction manual.

To disassemble 585C piston actuators sizes 60 and 68 (with handwheel) for maintenance, perform the following procedures (figure 10 and 12):

1. Be sure that all pressure is out of the cylinder and valve body.
2. Remove all tubing lines to the positioner.
3. Remove the cap screws (key 2) on the underside of either the cylinder flange (key 100) for size 60 or the adapter flange (key 76) for size 68. Remove the cylinder (key 1).
4. Remove the piston nut (key 4), then use a mallet to tap the piston (key 3) off the piston connector (key 107).
5. Remove the handwheel extension (key 117) by loosening the set screw (key 139) and unscrewing the extension. Loosen the hex nut (key 119) and the lockwasher (key 120) to remove the handwheel unit (key 118, 121, 122, and 123) from the bevel pinion (key 116). Slide the bevel pinion (key 116) out of the handwheel extension (key 117) and slide the bushing (key 124) out of the bevel pinion (key 116). Inspect the bushing (key 124) and the bevel pinion (key 116) for wearing or damage, and replace with new parts as needed. The bushing (key 124) is a directional design and its insider radius should be installed to the bevel pinion (key 116) gear side mating with the bevel pinion shoulder radius as shown in figure 4.

Figure 4. Fisher 585C Size 60 and 68 Handwheel Directional Bushing Design and Installation

6. Remove the cap screws (key 2) holding the cylinder flange (key 100) to the yoke (key 6).
7. Lift the cylinder flange (key 100) off the yoke (key 6).
8. Inspect the handwheel bearing retainer (key 113), bevel gear (key 114) and thrust bearing (key 115). Replace damaged parts as needed.
9. To remove the actuator stem (not shown), loosen the stem connection (key 12) and pull the actuator stem out the top of the sleeve assembly (key 104).
10. Remove the sleeve by screwing it out of the sleeve assembly (key 104).
11. Unscrew the seal bushing (key 110) to inspect the O-rings (keys 9 and 27).

Disassembly of Handwheel Constructions (Sizes 80-130)

⚠ WARNING

Refer to the WARNING at the beginning of the Maintenance section (Sizes 60-130) in this instruction manual.

To disassemble 585C piston actuators sizes 80-130 (with handwheel) for maintenance, perform the following procedures (figure 12):

1. Be sure that all pressure is out of the cylinder and valve body.
2. Remove all tubing lines to the positioner.
3. Remove the cap screws (key 2) on the underside of the cylinder adapter (key 101) and remove the cylinder (key 1).
4. Remove the piston nut (key 4), then use a mallet to remove the piston (key 3) from the piston connector (key 107).
5. Remove the cap screws (key 127) and cylinder adaptor (key 101).
6. Remove the cap screws (key 128) and remove the spacer (key 102), being careful not to lose the key (key 144).
7. Remove the locking pin (key 131), disconnect the stem connector (key 12) and pull out the actuator stem.
8. Remove the pointer (key 129) and turn the sleeve out of the sleeve assembly (key 104).
9. Remove the cap screws (key 128) holding the gear case (key 103) to the yoke (key 6).
10. Lift the gear case (key 103) to expose the handwheel assembly.

Reassembly (Sizes 60-130)

When reassembling the 585C piston actuator with side-mounted handwheel, adjust the setscrew (key 125) to eliminate play in gear bearings. When properly set, lock with key 126.

When reassembling the side mounted handwheel, all parts required lubrication as shown in per figure 10, 11, 12, and 13 should be fully lubricated.

When reassembling the actuator after the piston nut (key 4) has been removed from the piston connector (key 107), clean the threads of the piston nut thoroughly and apply thread sealant to the threads. Tighten the piston nut securely to a torque of 237 N•m (175 lbf•ft) for size 60 actuators, 1290 N•m (950 lbf•ft) for size 68, 80, and 100 actuators, or 2070 N•m (1530 lbf•ft) for size 130 actuators.

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, refer to the serial number found on the actuator nameplate (key 21).

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Sizes 25 and 50

Common Actuator Parts (figure 5 or 7)

Key	Description
1	Cylinder
2	Cylinder-to-Yoke Bolts
3	Piston
4	Cap Screw, for actuators without handwheel
5	Travel Stop Spacer
6	Yoke
7*	Yoke O-ring
8*	Piston O-ring
9*	Actuator Stem O-ring
10	Actuator Stem
11*	Piston Stem Bearing
12	Stem Connector
13	Stem Connector Nut
14	Cap Screw (2 req'd)
15	Hex Nut
16	Bias Spring, outer (see table 4-7 for use)
17	Bias Spring, inner (see table 4-7 for use)
18	Self Tapping Screw (2 req'd)
19	Travel Indicator Scale
20	Drive Screw (7 req'd)
21	Nameplate
22	Warning Tag
23	Hex Nut (2 req'd)
24	Lithium grease (not furnished with actuator)
25*	Back-Up Ring, Size 50 only
71	Warning Nameplate
75	Spacer (2 req'd)

Additional Parts for Actuator with Handwheel (figure 6, 8, or 9)

Key	Description
1	Cylinder,
35	Neutral Indicator Cover
36	Handwheel Housing
37	Neutral Indicator Plate
38	Bearing Cover
39	Thrust Bearing
40	Anti-rotation Key
42	Neutral Indicator
43	Neutral Indicator Plate Screw (2 req'd)
45	Handwheel Stem Washer
46	Operating Nut
47	Handwheel
48	Handwheel Retaining Ring
50	Grease Fitting
51	Bearing Cover Set Screw (3 req'd)
52	Handwheel Jam Nut
53	Button Plug
56	Handwheel Stem
57*	Cylinder Cover O-Ring - For Push Only
58*	Handwheel Housing O-Ring - For Push Only
60	Handwheel Stem Cap Screw, (4 req'd for size 25), (3 req'd for size 50)
63	Detent Spring
64	Detent Ball
65	Locking Key
66	Bypass Valve
67	Bypass Tubing
68	Bypass Tee
69	Piston Stud
70	Thread locking adhesive (medium strength) (not furnished with actuator)
72	Hex Nut, Slotted
73	Cotter Pin
74	Elbow, Tube

Introduction

Scope of Manual

This instruction manual provides information on installation, adjustment, maintenance, and parts ordering for the Fisher 644 and 645 differential pressure pump governors. Refer to separate instruction manuals for information about the valve and other accessories used with these governors.

Do not install, operate, or maintain 644 or 645 governors without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

Description

644 and 645 actuators are used in combination with any of several sliding-stem valves to automatically control steam-driven boiler feedwater pumps (reciprocating or turbine). The 644 or 645 actuator (see figures 1 and 2), when used in combination with one of several push-down-to-close sliding-stem valves, forms a pump governor.

644 and 645 actuators may also be combined with push-down-to-open valves to be used as relief governors. Relief governors are used to divert excess pump discharge back to the suction side of the pump.

Figure 2. Typical Pump Governor Sectionals

⚠ WARNING

These governors must be installed, operated, and maintained in accordance with Fisher instructions and all applicable federal, state, and local codes, laws, rules and regulations.

If a leak develops in the system or if any of the equipment is damaged, service is required. Failure to investigate problems immediately may cause a hazardous condition.

Call a serviceman in case of trouble. Only a qualified person must install or service the actuator.

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.

To avoid personal injury or property damage caused by bursting of pressure-retaining parts, be certain the service conditions do not exceed the casing pressure limit (maximum ΔP across the diaphragm) of 13.8 bar (200 psi). Use pressure-limiting or pressure-relieving devices to prevent service conditions from exceeding this limit.

Check with your process or safety engineer for any other hazards that may be present from exposure to process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

Normal operating temperature range for the 644 actuator is from -40 to 82°C (-40 to 180°F). For the 645 actuator, the range is from -37 to 82°C (-35 to 180°F).

Figure 3. Typical Installation for a Direct-Acting Governor

Direct-Acting Actuators

Proceed as follows to install 644 and 645 actuators that are used with push-down-to-close valves (644-ED, 645-ED). Refer to figure 3.

1. Place the governor in the steam line between a hand operated throttle valve (C) and the steam inlet to the pump. The governor may be installed in any position, as long as the flow is in the direction of the arrow cast on the valve body. However, when used for steam service, the unit should be installed so condensate will drain back into the diaphragm casing and maintain a water seal on the diaphragm. Failure to do so may impact performance.
2. Install a hand-operated throttle valve (E) between the governor and the steam supply line.
3. Run a 1/4-inch control line from the upper diaphragm casing to the side or top of the pump discharge line. Keep the control line away from any nipple, swage, or elbow.
4. Install a lock-shield needle valve (B) and a pressure gauge in this control line.
5. Run a second 1/4-inch control line from the lower diaphragm casing to the boiler steam pressure line. Install a needle valve (A) in this line. Slope the line toward the actuator in order to form a water seal on the diaphragm.
6. Connect the two control lines with an equalizing line in which a needle valve (F) has been installed.

Figure 4. Typical Installation for a Relief Governor

14A2789-A
A1763

CAUTION

The equalizing line helps prevent damage to the diaphragm when the system is started up.

Reverse-Acting Actuators

Proceed as follows to install 644 and 645 actuators that are used with push-down-to-open valves (644-EDR, 645-EDR).

Table 3. Maximum Static Casing Pressures

Diaphragm Casing Material		Cast Iron	Steel
Valve Body Ratings		CL125 and CL250	CL150, CL300 and CL600
Actuator	644	300 psig	600 psig
	645	500 psig	1000 psig

- Place the governor in the steam line. It may be installed in any position as long as the flow is in the direction of the arrow cast on the valve body. However, when used for steam service, the unit should be installed so condensate will drain back into the diaphragm casing and maintain a water seal on the diaphragm. Failure to do so may impact performance.
- Run a bypass line from the pump's discharge line to the suction line of the pump. In this line, install a hand-operated throttle valve (D).
- Run a 1/4-inch control line from the upper diaphragm casing to the pump discharge line. Install a needle valve (B) in this line.
- Extend a second 1/4-inch control line from the lower diaphragm casing to the boiler steam pressure line. Place a needle valve (A) in this line.
- Connect the two control lines with an equalizing line in which a needle valve (F) has been installed.

Overpressure

WARNING

Overpressuring any portion of this equipment may cause damage to the governor parts, leaks in the system, or personal injury due to bursting of pressure-containing parts.

To avoid overpressure, provide an appropriate overpressure protection device to ensure that none of the limits listed in table 3 will be exceeded.

Check the system for damage after any overpressure condition.

Startup

Proceed as follows to start up direct-acting actuators (644-ED, 645-ED). See figure 3.

1. Close all valves except the bypass valve (D).
2. Open the equalizing valve (F).
3. Open the needle valve (B) in the pump discharge line approximately 1/2 turn.
4. Open needle valve (A) in the pressure control line and close equalizing valve (F).
5. Open valve (C) that is downstream of the governor. Close bypass valve (D).
6. Slowly open valve (E) which is upstream of the governor.
7. To increase the discharge pressure, if it is too low, turn the lower spring seat (key 19, figures 6 and 7) clockwise into the yoke.
8. If the discharge pressure is too high, slightly open needle valve (B). If the pressure does not fall to the desired setting, turn the lower spring seat counterclockwise out of the yoke.
9. Open or close the lock-shield needle valve (B) to a point where a very slight movement of the valve stem (approximately 1/64-inch) is noticeable with each stroke of the pump. Greater stem movement will result in erratic operation and shorten the life of the diaphragm.

To start up reverse-acting actuators (644-EDR, 645-EDR) proceed as follows. See figure 4.

1. Close all valves except the bypass valve (D).
2. Open the equalizing valve (F).
3. Open valve (A) that is in the boiler pressure control line.
4. When the pump has built up the discharge pressure, open valve (B) that is in the discharge pressure control line. Close equalizing valve (F).
5. Valve (C), downstream of the governor, should now be opened. Close bypass valve (D).
6. Slowly open upstream valve (E).
7. To increase the discharge pressure if it is too low, turn the lower spring seat (key 19, figures 6 and 7) clockwise into the yoke.
8. If discharge pressure is too high, slightly open equalizing valve (F). If the pressure does not fall low enough, turn the lower spring seat counterclockwise out of the yoke.
9. Open or close valve (B) to a point where very slight movement (approximately 1/64-inch) of the stem is noticeable with each stroke of the pump. Greater stem movement will result in erratic operation and shorten the life of the diaphragm.

Adjustment

No adjustment is required other than that described in the procedure for putting the governor into operation. If it is necessary to change the setting, turn the lower spring seat clockwise into the yoke to increase the pressure setting. Turn the lower spring seat counterclockwise, out of the yoke, to decrease the pressure setting.

Principle Of Operation

Figure 3 shows a 645-ED being used to directly maintain a differential setting between the pump discharge pressure and the boiler steam pressure in a boiler feedwater system.

If pump discharge pressure increases, the change is registered on the top of the actuator diaphragm. The increased pressure forces the diaphragm and valve plug downward. With the steam supply thus restricted, less steam reaches the pump. This causes the discharge pressure to drop so that a difference between the discharge pressure and the boiler pressure will return to the desired differential setting.

In figure 4, a 644-EDR is being used as a relief governor maintaining a differential pressure between the boiler and pump discharge.

An increase in the pump discharge pressure is registered on the top of the actuator diaphragm. The increased pressure forces the diaphragm and valve plug downward. Since this governor is reverse-acting, this action opens the valve and allows the excess pump discharge to flow to the pump suction line. The pump discharge pressure drops and the difference between the boiler pressure and the pump discharge pressure returns to the desired level.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced when necessary. The frequency of inspection and replacement depends on the severity of service conditions.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any other hazards that may be present from exposure to process media.

⚠ WARNING

To avoid personal injury and equipment damage, isolate the pump governor from all pressure before beginning disassembly. The pump governor can be isolated by throttling valve (D) and closing the shut-off valves (A, B, C, and E).

Disassembly

Refer to figures 6 and 7.

1. Remove the control line from the upper casing.
2. Relieve spring compression by turning the lower spring seat (key 19) clockwise into the yoke.
3. Disconnect the stem (key 22) and the diaphragm rod (key 14) by unscrewing the locknuts (key 31).

CAUTION

To avoid damage to the valve plug and seating surface, do not turn the stem while the valve plug is seated.

4. Unscrew hex nuts (key 9) and remove the packing box flange (key 7) and the packing follower (key 6).
5. Remove cap screws (key 23) and hex nuts (key 24) and lift off the upper diaphragm casing (key 1).
6. Lift off the upper diaphragm head (key 29). Pull the diaphragm (key 3), lower diaphragm head (key 13), and the diaphragm rod (key 14) out of the lower diaphragm casing (key 2). (A travel stop or washer, key 17, figure 6, may also be present between the lower diaphragm head and locknut.) Do not change the position of the lower diaphragm head and locknut (key 15) on the diaphragm rod because they are set to give the proper clearance for valve travel.
7. With a wire hook, pull the packing (key 11, figure 6; key 12, figure 7) from the bottom of the lower diaphragm casing. Remove the spacer (key 5) and the upper piece of packing (key 12, figure 6; key 11, figure 7) in the same manner.

Reassembly

Note

Bearings and adjusting screw threads should be lubricated with anti-seize prior to the reassembly steps below.

644 (figure 6)

1. Install packing onto the diaphragm rod (key 14) from the bottom of the lower diaphragm casing (key 2) in the following order:

For PTFE packing:

- a. Bushing (key 10, if previously removed), packing spring (key 5), special washer (key 37), male adaptor (key 28), packing rings (key 12, 3 required), female adaptor (key 38), packing follower (key 6) and felt wiper ring (key 39.)

For graphite packing:

- a. Bushing (key 10, if previously removed), packing ring (key 11), packing ring (key 12, with zinc washer), packing ring (key 11), lantern ring (key 5), packing ring (key 11), packing ring (key 12, with zinc washers between, 2 each required), packing ring (key 11) and packing follower (key 6).

2. Replace the packing flange (key 7.)

3. Lubricate the packing flange studs (key 8) and the faces of the packing flange nuts (key 9) and install the packing flange nuts (torque: 26 lbf•in for PTFE, 53 lbf•in for graphite.)
4. Place a new diaphragm (key 3) on the lower diaphragm head (key 13).
5. Put the upper diaphragm head (key 29) onto the diaphragm. Set the upper diaphragm casing (key 1) onto the lower casing, lubricating and tightening the diaphragm casing cap screws (key 23) and hex nuts (key 24) finger-tight only.
6. Reconnect the connecting rod (key 22) and the diaphragm rod.
7. Turn the lower spring seat counterclockwise out of the yoke to remove slack from the diaphragm. Torque the diaphragm casing cap screws and nuts to the following:
 - a. Size 1: 29 lbf•ft.
 - b. Sizes 2 and 3: 67 lbf•ft.

Note

For 644 reverse-acting, travel stops (key 17) are required to be installed between the lower diaphragm head and the hex jam nut (key 15.) See the Parts List for the type and quantity of travel stops required for each actuator size.

645 (figure 7)

1. Install packing onto the diaphragm rod (key 14) from the bottom of the lower diaphragm casing (key 2) in the following order:

For PTFE packing:

- a. Packing box ring (key 10, if previously removed), packing spring (key 5), special washer (key 28), packing set (key 11), and packing follower (key 6).

For graphite packing:

- a. Packing box bushing (key 10, if previously removed packing ring (key 11), packing ring (key 12, with zinc washer), packing ring (key 11), lantern rings (key 5, 2 required), packing ring (key 11), packing rings (key 12, with zinc washers between, 2 each required), packing ring (key 11) and packing follower (key 6).
2. Replace the packing flange (key 7.)
3. Lubricate the packing flange studs (key 8) and the faces of the packing flange nuts (key 9) and install the packing flange nuts (torque: 58 lbf•in for PTFE, 122 lbf•in for graphite.)
4. Place a new diaphragm (key 3) on the lower diaphragm head (key 13).
5. Put the upper diaphragm head (key 29) onto the diaphragm. Set the upper diaphragm casing (key 1) onto the lower casing, lubricating and tightening the diaphragm casing studs (key 23) and hex nuts (key 24) finger-tight only.
6. Reconnect the connecting rod (key 22) and the diaphragm rod.
7. Turn the lower spring seat counterclockwise out of the yoke to remove slack from the diaphragm. Torque the diaphragm casing studs and hex nuts to 385 lbf•ft.

Note

For 645 reverse-acting, two washers (key 17) are required to be installed as shown in figure 7.

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always mention this number when corresponding with your [Emerson sales office](#) or Local Business Partner regarding technical information or replacement parts. Also, reference the complete 11-character part number of each needed part as found in the following Parts List.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

Scope of Manual

This instruction manual provides installation, adjustment, maintenance, and parts ordering for the Fisher 655 and 655R actuators and the top-mounted handwheel. Refer to separate instruction manuals for information about valves and accessories used with these actuators.

Do not install, operate, or maintain 655 or 655R actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

Table 1. Specifications

Description

655 and 655R actuators (figure 1) are pressure-actuated, spring-and-diaphragm actuators used in conjunction with various valves to provide control for a wide variety of pressure regulation applications. 655 actuators are used for pressure-reducing service when mounted on push-down-to-close valves such as the Fisher ED and ET valves. 655R actuators are used for pressure-relief service when mounted on push-down-to-open valves such as the Fisher EDR and ETR valves. Both types are self-operated and direct-acting; that is, increasing pressure in the diaphragm casing forces the actuator stem downward, and decreasing the pressure allows the actuator spring to lift the actuator stem upward.

Specifications

Specifications for the 655 and 655R actuators are shown in table 1. Information for a specific actuator is also found on the nameplate of that actuator.

Installation

⚠ WARNING

To avoid personal injury or property damage caused by bursting of pressure-retaining parts, be certain the service conditions do not exceed the casing pressure limits listed in table 1. Use pressure-limiting or pressure-relieving devices to prevent service conditions from exceeding these limits.

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

655 and 655R actuators are normally shipped mounted on a valve. Refer to the appropriate valve instruction manual when installing the valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the procedures described in the Actuator Mounting portion of this section.

CAUTION

To avoid premature wear of the diaphragm due to debris in the pressure line to the diaphragm, install a strainer in the pipeline ahead of the regulator or relief valve.

Before installing the actuator, inspect it for any damage. Also, keep any adjacent piping clean and free of pipe scale or other debris that could possibly disrupt service. It is recommended that a strainer be installed in the pipeline ahead of the regulator or relief valve to protect it while in service. And a conventional three-valve bypass (see figure 2) should be placed around the regulator or relief valve to permit continuous operation when it is being installed or repaired.

Actuator Mounting

The actuator may be installed either above or below the pipeline.

CAUTION

In steam service applications, avoid premature wear of the diaphragm, due to high temperature steam, by installing the valve with the actuator positioned below the pipeline.

If the regulator or relief valve is to be used for steam service, the valve should be installed with the actuator positioned below the pipeline, and the control line should be sloped down toward the diaphragm casing. This is to ensure that any forming condensate will maintain a water seal to protect the diaphragm.

The following procedure describes how to mount the actuator on either a push-down-to-close or a push-down-to-open valve so that the actuator stem and valve stem thread engagement will allow full travel and proper shutoff. Refer to figure 3 for actuator mounting components. Key numbers refer to figure 4 unless otherwise stated.

1. Turn the adjusting screw (key 10) into the yoke (key 7) to force the diaphragm (key 2) and diaphragm plate (key 4) against the upper diaphragm casing (key 1).
2. Perform the following steps as appropriate for either push-down-to-close or push-down-to-open valve action.

CAUTION

In the following procedures, do not rotate the valve plug while it is seated since this may cause damage to the seating surfaces and thereby allow excessive leakage. Also, during travel adjustment, use tools carefully to avoid damaging the valve plug stem. A damaged stem could cut the packing and allow leakage.

For Push-Down-To-Close Valves:

- a. Place the actuator part way over the valve stem. Then, place the yoke locknut over the valve stem, and slide the travel indicator disk (key 11, if used) on top of the hex nuts (key 12).
- b. Set the actuator onto the valve body. The length of the valve stem will prevent the actuator yoke (key 7) from sitting on the bonnet properly. Measure the distance from the bottom of the actuator yoke to the mating shoulder on the bonnet, and then add the valve plug travel to this measurement.
- c. Raise the actuator so the valve plug can be lifted off the seat ring.

Note

Either turn the actuator, or tighten the hex nuts together, and use a wrench on the hex nuts to turn the valve plug and stem assembly.

Thread the valve stem into the actuator stem the distance measured in the previous step.

- d. Lower the actuator onto the valve body bonnet, and tighten the yoke locknut.
- e. Connect the pressure control lines as described in the Loading Connection portion of this section.
- f. Stroke the actuator, and measure the stem movement to check travel. If the movement is more than full travel, turn the valve stem out of the actuator stem the amount of over-travel. If movement is less than full travel, turn the valve stem into the actuator stem the amount of under-travel.

For Push-Down-To-Open Valves:

- a. Place the actuator, yoke locknut, and travel indicator disk (key 11, if used) over the valve stem. Support the actuator above the valve body so the actuator stem and valve stem do not contact when the valve plug is seated.
- b. Connect the pressure control lines as described in the Loading Connection portion of this section.
- c. Move the valve plug, by hand, from the seated to the open position, and make sure that valve stem movement corresponds to the desired travel.
- d. Stroke the actuator until the diaphragm plate (key 4) contacts the down travel stop (see figure 3).
- e. With the valve plug positioned as described in step c above, lower the actuator until the actuator stem contacts the valve stem, and measure the distance from the bottom of the actuator yoke to the mating shoulder on the bonnet.
- f. Thread the valve stem into the actuator stem until the thread engagement is equal to the distance measured in the previous step. Tighten the hex nuts (key 12) together, and use a wrench to turn the valve plug and stem assembly.
- g. Lower the actuator onto the valve body bonnet, and tighten the yoke locknut.
- h. Stroke the actuator, and measure the stem movement to check travel. If the movement is more than full travel, turn the valve stem into the actuator stem the amount of over-travel. If the movement is less than full travel, turn the valve stem out of the actuator stem the amount of under-travel.

1. For the spring rates of a particular spring, see key 6 in the Parts List section.

Figure 3. Actuator/Valve Components

DV3742-B
DH4667-B
31A0223-B
B0816-1

PUSH-DOWN-TO-CLOSE VALVE

PUSH-DOWN-TO-OPEN VALVE

3. After correct travel has been obtained, tighten the hex nuts (key 12) against the actuator stem (key 8), and tighten the yoke locknut with a hammer and punch.

Note

Changing the spring adjustment will not change the actuator pressure range for that particular spring (see table 2). Changing the spring adjustment merely shifts the position of the spring either up or down so that valve travel can coincide with the actuator pressure setting range.

4. While monitoring loading pressure with a pressure gauge, stroke the actuator, and then turn the adjusting screw until the valve begins to travel at the desired pressure. Turn the adjusting screw out of the yoke to decrease spring compression and thus allow the valve to begin travel at a lower loading pressure. Turn the adjusting screw into the yoke to increase spring compression and thus allow the valve to begin travel at a higher loading pressure.

Loading Connections

Install the control line following the steps listed below. Typical installations are shown in figure 2.

1. Connect the control line into either the upstream pipeline for pressure-relief service or into the downstream pipeline for pressure-reducing service as shown in figure 2. Make the pipeline tap at least four to eight pipe diameters away from the regulator or relief valve, or any elbow, swage, or nipple, to avoid abnormal velocities or turbulence.
2. Connect the other end of the control line to the 1/2 NPT connection in the center of the upper diaphragm casing (key 1) or to the connection in the handwheel body (key 28, figures 6 and 7; key 142, figure 5).
3. Fit the control line with a large-port needle valve. Partially closing or throttling this valve will tend to dampen any cycling or pulsating action of the regulator. Never completely close the needle valve while the regulator is in operation.

Startup

The procedures for placing into operation and adjusting the equipment for both pressure-reducing and pressure-relief applications are described below. Typical installation schematics are shown in figure 2.

Startup For Pressure-Reducing Service

1. Open the needle valve in the control line.
2. Open the downstream shutoff valve.
3. Close the valve in the bypass line.
4. Slowly open the upstream shutoff valve.

Startup For Pressure-Relief Service

1. Open the needle valve in the control line.
2. Open the downstream shutoff valve.
3. Slowly open the upstream shutoff valve.
4. Close the valve in the bypass line.

Adjustment For Pressure-Reducing or Pressure-Relief Service

The actuator is factory-set as specified on the order, and the pressure range is stamped on the nameplate. If a pressure setting other than the one specified is desired, change the pressure setting by following the procedures listed below. Be sure to change the nameplate to indicate the new pressure setting. The new pressure setting must not exceed the limits given in tables 1 and 2 or in any applicable codes.

CAUTION

To protect equipment in the process system from a sudden release of pressure, always use a pressure gauge to monitor pressure when making adjustments.

To adjust the downstream pressure setting for pressure-reducing service, or the upstream pressure setting for pressure-relief service, proceed as follows. To decrease the pressure setting, turn the adjusting screw (key 10, figure 4) counterclockwise; to increase the pressure setting, turn the adjusting screw clockwise. If the spring does not provide the required pressure setting, replace it through the following steps:

1. Disassemble the actuator by following steps 1, 3 and 4 of the Disassembly portion of the Maintenance section.
2. Remove the diaphragm (key 2). Then, unscrew the cap screw (key 3), and lift the diaphragm plate (key 4) out of the actuator body.
3. Replace the spring and reassemble the actuator by following steps 5 and 6 of the Assembly portion of the Maintenance section.

Shutdown

For both pressure-reducing and pressure-relief applications, refer to figure 2, and follow the procedures described below.

1. Close the upstream shutoff valve slightly.
2. Slowly open the bypass valve while monitoring downstream pressure.
3. Slowly close the downstream shutoff valve.
4. Close the upstream shutoff valve.
5. Close the needle valve in the control line.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced when necessary. The frequency of inspection and replacement depends on the severity of service conditions.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

The maintenance instructions are divided into two sections: Actuator and Top-Mounted Handwheel.

Actuator

This procedure describes how the actuator can be completely disassembled and assembled. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job; then, start the assembly at the appropriate step.

Key numbers refer to figure 4.

Disassembly

CAUTION

In the following procedure, do not rotate the valve plug while it is seated since this may cause damage to the seating surfaces and thereby allow excessive leakage. Also, during travel adjustment, use tools carefully to avoid damaging the valve plug stem. A damaged stem could cut the packing and allow leakage.

1. Rotate the handwheel (if one is used) counterclockwise to be sure the handwheel is not compressing the spring (key 6).
2. For complete disassembly, the actuator must be removed from the valve, and the actuator stem (key 8) must be completely disengaged from the valve plug stem by rotating the actuator. Perform the appropriate procedure according to the respective valve action.

For Push-Down-To-Close Valves:

Note

To prevent the actuator stem (key 8) from rotating while performing the following procedure, make sure the adjusting screw (key 10) remains screwed into the yoke (key 7).

- a. Loosen the two hex nuts (key 12).
- b. Loosen the yoke locknut (figure 3) with a hammer and punch, and unscrew it from the valve bonnet.
- c. While lifting the actuator so that the valve plug is not forced against the seat, rotate the entire actuator until the actuator stem disengages completely from the valve plug stem.

For Push-Down-To-Open Valves:

- a. Turn the adjusting screw (key 10) counterclockwise to relieve all spring compression. Then, move the valve plug, by hand, off the seat.
 - b. Loosen the hex nuts (key 12), and unscrew the valve plug stem out of the actuator stem as far as it will go.
 - c. Turn the adjusting screw into the yoke (key 7) to force the diaphragm (key 2) and diaphragm plate (key 4) against the upper diaphragm casing (key 1).
 - d. Loosen the yoke locknut (figure 3) with a hammer and punch, and unscrew it from the valve bonnet.
 - e. Rotate the entire actuator until the actuator stem disengages from the valve plug stem.
3. Turn the adjusting screw (key 10) counterclockwise out of the yoke (key 7) to relieve all spring compression.
 4. To remove the upper diaphragm casing (key 1), unscrew the cap screws (key 19) for size 3A and 4A actuators or the cap screws and hex nuts (keys 19 and 20) for all other sizes.
 5. Remove the diaphragm (key 2); then, lift the diaphragm plate (key 4) and actuator stem assembly out of the actuator body. Also, remove the spring and the lower spring seat (key 9).
 6. For size 3A and 4A actuators, remove the lower diaphragm casing (key 5).
 7. Remove the cap screw (key 3), and separate the diaphragm plate from the actuator stem.
 8. For size 3B through 46 actuators, unscrew the cap screws (key 21), and remove the lower diaphragm casing (key 5). Some 655R actuators will have travel stops (key 13, not shown) in place of three of these six cap screws.
 9. If a top-mounted handwheel assembly is used, refer to steps 4 through 8 of the Disassembly portion of the Top-Mounted Handwheel section.

Assembly

This procedure assumes that the actuator is completely disassembled. If it is not, start the instructions at the appropriate step.

1. Before starting assembly, apply moly-grease lubricant to the threads and the bearing end of the adjusting screw (key 10) as indicated in figure 4 by the letter A.
2. For size 3A and 4A actuators, set the lower diaphragm casing (key 5) onto the yoke (key 7).
3. For size 3B through 46 actuators, install the lower diaphragm casing (key 5), and secure it with the cap screws (key 21). Some 655R actuators will have travel stops (key 13, not shown) in place of three of these six cap screws.
4. Install the lower spring seat (key 9) and the actuator spring (key 6).

Note

To take some of the slack out of the diaphragm (key 2) at the bolt circle, turn the adjusting screw into the yoke (key 7) to raise the diaphragm plate (key 4). This will also ensure that the diaphragm will have enough slack inside the casings for efficient travel.

5. Secure the diaphragm plate (key 4) to the actuator stem (key 8) with the cap screw (key 3), and install this assembly into the actuator. Install the diaphragm, making sure that the patterned side of the diaphragm is next to the diaphragm plate.

Note

When replacing the upper diaphragm casing (key 1), be sure there are no wrinkles in the diaphragm that might cause the diaphragm to tear or allow leakage.

6. Place the upper diaphragm casing onto the lower diaphragm casing. For size 3A and 4A actuators, secure the casings with the cap screws (key 19). For all other actuator sizes, secure the casing with the cap screws and hex nuts (keys 19 and 20).

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench.

CAUTION

Over-tightening the diaphragm cap screws (key 19) or cap screws and nuts (keys 19 and 20) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

7. Install the upper diaphragm casing (key 1), and install the cap screws (key 19) or cap screws and nuts (keys 19 and 20). Tighten in the following manner.
8. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 13 N•m (10 lbf•ft).
9. Tighten the remaining bolts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
10. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
11. Tighten the remaining bolts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
12. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
13. Once completed, no more tightening is recommended.
14. Mount the actuator onto the valve by following the procedures outlined in the Actuator Mounting portion of the installation section.
15. Connect the pressure control line by following the procedures outlined in the Loading Connections portion of the Installation section.
16. To start up and adjust the actuator, follow the procedures outlined in the Startup section of this instruction manual.

Top-Mounted Handwheel

Top-mounted handwheel assemblies (figures 6, 7 and 5) are normally used as adjustable travel stops to limit full upward travel of the actuator stem. Turning the handwheel clockwise forces the actuator stem downward, while turning the handwheel counterclockwise allows the spring to force the actuator stem upward. If the actuator is used with a push-down-to-close valve, full opening of the valve plug can be restricted through the appropriate positioning of the top-mounted handwheel. If the actuator is used with a push-down-to-open valve, closing of the valve plug can be restricted by using the handwheel. A locknut (key 27, figures 6 and 7; key 137, figure 5) is used to hold the handwheel in position.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Key numbers refer to figure 6 for size 3A and 4A, figure 7 for size 3B and 4B, and figure 5 for size 32 through 46 top-mounted handwheel assemblies.

Disassembly

1. Bypass the control valve. Relieve all loading pressure, and remove the tubing or pipe from the handwheel body.
2. Loosen the hex nut (key 27, figures 6 and 7; key 137, figure 5). Turn the adjusting screw (key 10, figure 4) and the handwheel (key 25, figures 6 and 7; key 51, figure 5) counterclockwise to relieve all compression.
3. For size 3A and 4A actuators, remove the cap screws (key 19, figure 4), and lift the handwheel body (key 28, figure 6) off the actuator.
4. For size 3B through 46 actuators, remove the cap screws and hex nuts (keys 19 and 20, figure 4), and then lift off the upper diaphragm casing (key 1, figure 4) and handwheel assembly. To replace the O-ring (key 139, figure 5) or for ease of handling, separate the handwheel assembly from the upper diaphragm casing. This can be accomplished by removing the cap screws that secure the handwheel assembly to the upper diaphragm casing (key 33, figure 7; key 141, figure 5).
5. Turn the handwheel clockwise two or three turns. Remove the hex nut (key 22, figures 6 and 7; key 54, figure 5) and washer (key 24, figures 6 and 7; key 134, figure 5), and lift off the handwheel.
6. Unscrew the locknut (key 27, figures 6 and 7; key 137, figure 5) from the handwheel stem (key 26, figures 6 and 7; key 133, figure 5), and then remove the handwheel stem through the bottom of the handwheel body (key 28, figures 6 and 7; key 142, figure 5). A screwdriver slot in the top of the handwheel stem is provided for this purpose.
7. Check the O-ring (key 29, figures 6 and 7; key 138, figure 5), and replace it if necessary.
8. To complete disassembly, drive out the groove pin (key 31, not shown; key 140, figure 5), and slide the pusher plate (key 32, figures 6 and 7; key 135, figure 5) off the handwheel stem. For 655, size 3B and 4B actuators, a travel stop (key 34, figure 7) should also be removed with these parts.

Assembly

This procedure assumes that the handwheel assembly is completely disassembled. If it is not, start the instructions at the appropriate step.

1. During assembly, apply lithium grease lubricant (key 241) to the handwheel stem and threads, the pusher, and to the O-rings as shown in figures 6, 7 and 5.
2. Slide the pusher plate (key 32, figures 6 and 7; key 135, figure 5) onto the handwheel stem, and, if necessary, insert the groove pin (key 31, not shown; key 140, figure 5). For 655, size 3B and 4B actuators, a travel stop (key 34, figure 7) should also be inserted on the handwheel stem with these parts.
3. Insert the handwheel stem into the handwheel body (key 28, figures 6 and 7; key 142, figure 5); then, screw the hex nut (key 27, figures 6 and 7; key 137, figure 5) onto the handwheel stem.

4. Install the handwheel (key 25, figures 6 and 7; key 51, figure 5) and washer (key 24, figures 6 and 7; key 134, figure 5) onto the handwheel stem, and secure it with the hex nut (key 22, figures 6 and 7; key 54, figure 5).
5. For size 3A and 4A actuators, set the handwheel body onto the actuator, and secure it with the cap screws (key 19, figure 4).

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench.

CAUTION

Over-tightening the diaphragm cap screws (key 19) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

6. Install the upper diaphragm casing (key 1), and install the cap screws (key 19). Tighten in the following manner.
7. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 13 N•m (10 lbf•ft).
8. Tighten the remaining bolts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
9. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
10. Tighten the remaining bolts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
11. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
12. Once completed, no more tightening is recommended. Proceed to step 21.
13. For size 3B through 46 actuators, set the upper diaphragm casing (key 1, figure 4) and handwheel assembly onto the actuator body, and secure it with the cap screws and hex nuts (keys 19 and 20, figure 4).

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench.

CAUTION

Over-tightening the diaphragm cap screws and nuts (keys 19 and 20) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

14. Install the upper diaphragm casing (key 1), and install the cap screws and nuts (keys 19 and 20). Tighten in the following manner.
15. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 13 N•m (10 lbf•ft).
16. Tighten the remaining bolts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
17. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
18. Tighten the remaining bolts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
19. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
20. Once completed, no more tightening is recommended.
21. Connect the pressure control line to the top-mounted handwheel assembly by following the procedures outlined in the Loading Connections portion of the Installation section.
22. To start up and adjust the actuator, follow the procedures outlined in the Startup section of this instruction manual.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, refer to the serial number found on the actuator nameplate (key 17, figure 4).

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for Fisher 656 diaphragm actuators. Refer to separate manuals for instructions covering the valve, positioner, and accessories.

Description

Fisher 656 actuators are long stroke, spring opposed, direct-acting diaphragm actuators. They operate Vee-Ball™ control valves, butterfly valves, built-in turbine valves, louvers, dampers and similar equipment. They are suitable for either push-down-to-close (PDTC) or push-down-to-open (PDTO) applications and are available in sizes 30, 40 and 60 to provide 54 mm (2.125 inch), 89 mm (3.5 inch) and 105 mm (4.125 inch) travel, respectively.

Do not install, operate, or maintain a 656 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Table 1. Specifications

Maximum Recommended Casing Operating Pressure⁽¹⁾

2.4 bar (35 psig)

Maximum Allowable Casing Pressure⁽²⁾

Actuator Size	Maximum Casing Pressure for Actuator Sizing ⁽²⁾ , Bar (Psig)	Maximum Excess Diaphragm Pressure ⁽¹⁾ , Bar (Psig)	Maximum Diaphragm Casing Pressure ^(2,3) , Bar (Psig)
30	8.6 (125)	1.0 (15)	9.7 (140)
40	4.5 (65)	0.69 (10)	5.2 (75)
60	2.8 (40)	0.69 (10)	3.4 (50)

1. Additional pressure may be added when the actuator is at full travel. If the Maximum Excess Diaphragm Pressure is exceeded, damage to the diaphragm or diaphragm casing might result. See the Maximum Pressure Limitation section.
2. Maximum diaphragm casing pressure must not be exceeded and must not produce a force on the actuator stem greater than the maximum allowable actuator output thrust or the maximum allowable stem load. See the Maximum Pressure Limitation section.
3. This maximum casing pressure is not to be used for normal operating pressure. Its purpose is to allow for typical regulator supply settings and/or relief valve tolerances.

Operating Temperature Range⁽³⁾

- -40 to 82°C (-40 to 180°F) with Nitrile Elastomer
- -40 to 149°C (-40 to 300°F) with Silicone Diaphragm

1. Control and stability may be impaired if this pressure is exceeded.
2. Exceeding this pressure can cause damage to the diaphragm, diaphragm casing, or other parts.
3. The temperature limits in this manual and any applicable standard or code limitation for valve should not be exceeded.

Casing Pressure Connection

1/4 NPT internal

Maximum Travel

ACTUATOR SIZE	MAXIMUM RATED STEM TRAVEL, mm (INCHES)	
	Standard Travel Stop	Optional Travel Stop
30	54 (2.125)	Not available
40	89 (3.5)	76 (3)
60	105 (4.125)	97 (3.8125)

Actuator Weight

Actuator Size	Approximate Shipping Weight, kg (Pounds)
30	23 (50)
40	32 (70)
60	73 (160)

Options

- Top-mounted handwheel/adjustable travel stop
- Casing-mounted adjustable down travel stop

Principle of Operation

In a direct acting diaphragm actuator, increasing loading pressure moves the actuator stem downward, compressing the spring. When the diaphragm pressure is decreased, the spring moves the actuator stem upward. In the event of failure of the loading pressure, the actuator stem moves to the extreme upward position.

Specifications

Refer to table 1 for Specifications of the 656 actuator. See the actuator nameplate for specific information for your actuator.

WARNING

To avoid personal injury or damage to equipment that may result in the malfunction of the control valve or loss of control of the process caused by excessive pressure, do not exceed the Maximum Pressures listed in table 1. Refer to the following Maximum Pressure Limitations section.

Maximum Pressure Limitations

The casing and diaphragm of 656 actuators are pressure operated. This air pressure provides energy to compress the spring, to stroke the actuator, and to seat the valve. The following explanations describe the maximum pressure limits for an actuator. Refer to the nameplate or table 1 for maximum values for your actuator.

- **Maximum Casing Pressure for Actuator Sizing:** This is the maximum pressure that can be applied at less than full travel of the actuator. If this stroking pressure is exceeded before the upper diaphragm plate contacts the travel stop, damage to the stem or other parts might result.
- **Maximum Excess Diaphragm Pressure:** Additional pressure may be added when the actuator is at full travel. If the Maximum Excess Diaphragm Pressure is exceeded, damage to the diaphragm or diaphragm casing might result.

Because the actuator has traveled its specified travel, and the diaphragm head is physically stopped from movement, the energy from any additional air pressure is transmitted to the diaphragm and diaphragm casings. The amount of air pressure that can be added once the actuator has traveled to the stops is limited by the resultant adverse effects that may occur. Exceeding this limiting factor could result in leakage or casing fatigue due to the deformation of the upper diaphragm casing.

- **Maximum Diaphragm Casing Pressure:** If the Maximum Diaphragm Casing Pressure is exceeded, damage to the diaphragm, diaphragm casing, or actuator might result.

Installation

When an actuator and valve are shipped together, the actuator is normally mounted on the valve. Follow the valve instructions when installing the valve and actuator in a pipeline. If the actuator is shipped separately, or if it is necessary to mount the actuator on the valve, four holes have been tapped into the yoke boss to anchor it to a mounting bracket.

WARNING

Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.

To avoid personal injury or property damage caused by bursting of pressure retaining parts, be certain the diaphragm casing pressure does not exceed the limits listed in the Specifications table. Use pressure relieving or pressure limiting devices to prevent the diaphragm casing pressure from exceeding these limits.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

To make the stem connection, follow the appropriate assembly step 10 in the Maintenance section. Standard actuator sizes 30 and 40 have mounting holes tapped 3/8 inch UNC, and the size 60 mounting holes are tapped 1/2 inch UNC.

A 1/4 NPT loading pressure connection is located in the top of the upper diaphragm case. Using either pipe or tubing, connect either the loading pressure connection or valve positioner input connection (if a valve positioner is furnished, the loading pressure connection to the actuator will be made at the factory) to the output pressure connection on the controller. Keep the length of the pipe or tubing as short as possible to avoid transmission lag in the control signal.

Adjustment

When the actuator is completely installed and connected to the controller, it should be checked for correct travel, freedom from friction and correct PDTC or PDTO action.

The actuator spring and diaphragm have been selected to meet the requirements of the application. It should be noted that the actuator spring has a constant rate of compression and that adjustment of the spring compression merely shifts the initial spring setpoint up or down to make the actuator travel within the initial spring setpoint and the maximum diaphragm pressure indicated on the nameplate.

In some instances, however, such as high friction butterfly and ball valves, the actuator will fully stroke with less diaphragm pressure than indicated on the nameplate. To increase the pressure required to initiate actuator stem movement, turn the lower bearing seat (key 14) up toward the spring case. To decrease the pressure at which movement begins, turn the lower bearing seat down, away from the spring case.

Maintenance

WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you are working on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Disassembly

1. If the actuator is installed on a control valve, isolate or bypass the control valve.
2. Shut off the diaphragm loading pressure and remove the pipe or tubing from the loading pressure connection in the top of the diaphragm case.
3. Turn the lower bearing seat (key 14) down, away from the spring case to relieve all spring compression.
4. If the entire actuator is to be removed from its mounting, disconnect the actuator stem (key 10) from the stem connector, clevis, etc., and remove the jam nuts (key 23). Loosen the cap screws that hold the yoke (key 9) to its mounting plate or bracket, and lift the entire actuator from its mounting.
5. Remove the diaphragm case cap screws and nuts (keys 19 and 20) and lift the upper diaphragm case (key 1) off the actuator. Remove the diaphragm (key 2).
6. Lift out the diaphragm plate (key 4) and stem (key 10). They may be separated by removing the cap screw (key 3).

Figure 2. Travel Stop Orientation for Size 60

7. Take out the actuator spring (key 6).
8. The lower diaphragm case (key 5) can be removed from the yoke, if required, by loosening the travel stops and cap screws (keys 7 and 8).
9. Remove the lower spring seat (key 11) and thrust bearing (key 13). Unscrew the lower bearing seat (key 14) from the adjusting screw (key 12).
10. Remove the set screw (key 22) and remove the adjusting screw to complete disassembly.

Assembly

1. Apply lithium grease lubricant, or equivalent, to the adjusting screw threads (key 12) and screw this into the yoke (key 9). Replace set screw (key 22). The set screw should engage the machined thread relief in the adjusting screw.
2. With the eared portion up, screw the lower bearing seat (key 14) all the way onto the adjusting screw.
3. Apply lithium grease lubricant, or equivalent, to the thrust bearing (key 13) and position it on the lower bearing seat (key 14). Lay the lower spring seat (key 11) on top of the thrust bearing assembly.
4. Mount the lower diaphragm case (key 5) to the top of the yoke (key 9) using the travel stops and cap screws (keys 7 and 8). Alternate screws and travel stops on the sizes 30 and 40. See figure 2 for the correct orientation of the size 60.
5. Position the actuator spring (key 6) on the lower spring seat.
6. Attach the diaphragm plate (key 4) to the actuator stem (key 10) with the cap screw (key 3). Apply lithium grease lubricant, or equivalent, to the stem. Place this assembly, actuator stem first, into the yoke with the actuator stem through the spring adjustor (key 12).
7. Position the diaphragm (key 2) on the diaphragm plate (key 4) and align the holes with the lower diaphragm casing (key 5). Attach the upper diaphragm case (key 1) to the lower diaphragm casing (key 5) using the cap screws and nuts (keys 19 and 20).

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

- a. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 13 N•m (10 lbf•ft).
 - b. Tighten the remaining bolts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
 - c. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
 - d. Tighten the remaining bolts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
 - e. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle. Once completed, no more tightening is recommended.
8. If the actuator has been removed from its mounting, position it on its mounting plate or bracket, and secure with cap screws.
 9. Attach the pressure pipe or tubing to the loading pressure connection on top of the upper diaphragm case.
 10. Attach the actuator stem to the stem connector or clevis and adjust the travel by using the appropriate procedure below.

For Push-Down-to-Open applications:

1. Set the controlled element (valve plug, louver, damper, etc.) in the closed position.
2. Turn the lower bearing seat (key 14) up toward the spring case far enough to ensure that the actuator stem is at the top of its stroke.
3. Make the actuator stem connection, making sure that there is full engagement of the actuator stem threads. Tighten slightly.
4. Apply loading pressure to the diaphragm case to move the controlled element toward its wide open position. Screw the controlled element linkage into the actuator stem connection far enough to move the controlled element toward its closed position 3.2 mm (1/8 inch), and tighten the stem connection securely. This adjustment ensures that the controlled element will close before the actuator stem travels to the top of its stroke. The travel stops (key 7) in the lower diaphragm case ensure correct travel of the controlled element in the open direction.
5. If travel starts at a lower or higher pressure than is required for proper operation, turn the lower bearing seat (key 14) up or down respectively, as described in the Adjustment section.

For Push-Down-to-Close applications:

1. Set the controlled element (valve plug, louver, damper, etc.) in the open position.
2. Turn the lower bearing seat (key 14) up toward the spring case far enough to ensure that the actuator stem is at the top of its stroke.
3. Tighten the actuator stem connection slightly, making sure that there is full engagement of the actuator stem threads.
4. Apply loading pressure to the diaphragm case and observe the travel of the controlled element to make sure that it closes completely. If the travel is not correct, it can be changed by screwing the controlled element linkage in or out of the stem connection. When the travel is set correctly, tighten the stem connection securely, and lock the jam nuts (key 23).
5. If travel starts at a lower or higher pressure than is required for proper operation, turn the lower bearing seat in or out respectively, as described in the Adjustment section.

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, refer to the serial number found on the actuator nameplate.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

Scope of Manual

This instruction manual provides information on installation, adjustment, maintenance, and parts ordering for the Fisher 657 actuator in sizes 30/30i through 70/70i and size 87. The 657-4 actuator in sizes 70/70i and 87 is also covered. Refer to separate instruction manuals for information about the valve positioner and other accessories used with these actuators.

Do not install, operate, or maintain a 657 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

1. These values also apply to the 657-4 actuator construction.
 2. Actuator travel may be less than the value listed after connecting the actuator to the valve.
 3. Maximum travel for 657-4 is 102 mm (4 inches).
 4. Normal operating diaphragm pressure must not exceed maximum diaphragm casing pressure and must not produce a force on the actuator stem greater than the maximum allowable output thrust or the maximum allowable valve stem load. Contact your [Emerson sales office](#) or Local Business Partner with questions concerning maximum allowable valve stem load.
 5. This maximum casing pressure is not to be used for normal operating pressure. Its purpose is to allow for typical regulator supply settings and/or relief valve tolerances.

Description

The 657 actuator (figure 1) and the 657-4 actuator are direct-acting, spring-opposed diaphragm actuators. They provide automatic operation of control valve body assemblies. The 657 actuator offers 76 mm (3 inches) maximum actuator travel. The 657-4 actuator provides 102 mm (4 inches) maximum actuator travel. Both actuators position the valve plug in response to varying pneumatic loading pressure on the actuator diaphragm. Figure 2 shows the operation of these actuators.

A 657 or 657-4 actuator can be equipped with either a top-mounted or a side-mounted handwheel assembly. A top-mounted handwheel assembly is used as an adjustable up travel stop to limit actuator travel in the up direction (see figure 2). A side-mounted handwheel assembly is usually used as an auxiliary manual actuator. Adjustable casing-mounted up or down travel stops are also available for this actuator.

Note

If repeated or daily manual operation is expected, the actuator should be equipped with a side-mounted handwheel rather than a casing-mounted travel stop or top-mounted handwheel.

The side-mounted handwheel is designed for more frequent use as a manual operator.

Specifications

Refer to table 1 for Specifications of the 657 and 657-4 actuators. See the actuator nameplate for specific information about your actuator.

Figure 2. Schematic of Fisher 657 and 657-4 Actuators

[Click here](#) or access the following QR code for a video on installing a side-mounted handwheel on a 657 actuator.

Installation

Key number locations are shown in figures 6, 7, 8, 9, and 10, unless otherwise indicated. Also, refer to figure 3 for location of parts.

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

CAUTION

To avoid parts damage, do not use an operating pressure that exceeds the Maximum Diaphragm Casing Pressure (table 1) or produces a force on the actuator stem greater than the Maximum Allowable Output Thrust (table 1) or the maximum allowable valve stem load. (Contact your [Emerson sales office](#) or Local Business Partner with questions concerning maximum allowable valve stem load.)

- **Valve/Actuator Assembly:** If the actuator and valve are shipped together as a control valve assembly, it has been adjusted at the factory, and may be installed in the pipeline. After installing the valve in the pipeline, refer to the Loading Connection procedures.
- **Actuator Mounting:** If the actuator is shipped separately or the actuator has been removed from the valve, the actuator should be mounted to the valve before placing the valve in the pipeline when practical. In the case of needing to place a weld-end body in-line, the trim will be removed from the body during the welding process. When completed and reassembled, the actuator should then be mounted to the welded in valve assembly. Refer to the actuator mounting procedures before placing the valve in service. You may perform the Bench Set Spring Adjustment procedures in this section to confirm the adjustment has not changed since it was shipped from the factory.
- **Positioner:** If a positioner is installed, or is to be installed on the actuator, refer to the positioner instruction manual for installation. During the adjustment procedures, it will be necessary to provide a temporary loading pressure to the actuator diaphragm.

Mounting the Actuator on the Valve

The 657 actuator spring loading pushes the actuator stem up towards the actuator diaphragm (see figure 2). This spring action moves the stem away from the valve while installing the actuator.

CAUTION

If the valve stem is allowed to remain in the up position (towards the actuator) during mounting, it can interfere with the actuator mounting, possibly damage valve stem threads or bend the valve stem. Be sure the valve stem is pushed down (into the valve body), away from the actuator while mounting.

Provide a temporary method of applying diaphragm loading pressure to the diaphragm to extend the actuator stem during bench set spring adjustments.

1. Provide a vise or some other method of supporting the valve and the weight of the actuator during assembly. For direct or reverse acting valves, push the valve stem down away from the actuator while mounting the actuator.
2. Screw the stem locknuts all the way onto the valve stem. With the concave side of the travel indicator disk (key 14) facing the valve, install the travel indicator disk on the valve stem. (Note: The travel indicator disk is not used with size 87 actuators.)
3. Lift or hoist the actuator onto the valve bonnet:
 - a. For size 87 actuators, insert the cap screws and tighten the hex nuts, securing the actuator to the bonnet.
 - b. For all other size actuators, screw the yoke locknut onto the valve bonnet and tighten the locknut. (Note: On small size actuators, it may be necessary to remove the indicator disk and re-install it while lowering the actuator on to the valve because the disk will not go through the actuator yoke opening.)

- Do not connect the actuator stem to the valve stem at this time. Whenever the actuator is installed on the valve, it is recommended to perform the Bench Set Spring Adjustment procedure to verify that the actuator is still adjusted correctly.

Figure 3. Actuator Mounting Components for Size 30/30i through 70/70i Actuators

Discussion of Bench Set

The bench set pressure values are used to adjust the initial compression of the actuator spring with the valve-actuator assembly “on the bench.” The correct initial compression is important for the proper functioning of the valve-actuator assembly when it is put into service and the proper actuator diaphragm operating pressure is applied.

The bench set values are established with the assumption that there is no packing friction. When attempting to adjust the spring in the field, it is very difficult to ensure that there is no friction being applied by “loose” packing.

Accurate adjustment to the bench set range can be made during the actuator mounting process by making the adjustment before the actuator is connected to the valve (see the Spring Verification procedure).

Figure 4. Bench Set Adjustment

NOTES:

- 1 THE LOWER PSIG LOADING PRESSURE (MARKED ON NAMEPLATE) WHERE THE FIRST MOVEMENT OF ACTUATOR STEM IS DETECTED.
- 2 THE UPPER PSIG LOADING PRESSURE EXTENDS ACTUATOR STEM.
- 3 MARK THIS POINT WITH TAPE OR A MARKER.
- 4 MEASURE DISTANCE OF TRAVEL. IT SHOULD EQUAL THE TRAVEL SPAN SHOWN ON THE NAMEPLATE.

40A8715-B
B2426

Spring Verification

Ensure that the actuator stem is at the top of its travel as shown in figure 4 and not connected to the valve. (Note: Some spring compression is required to move the diaphragm to the top of its travel.) The steps provided are the same for push-down-to-close (direct acting) or push-down-to-open (reverse acting) valves.

⚠ WARNING

When moving the actuator stem with diaphragm loading pressure, use caution to keep hands and tools out of the actuator stem travel path. Personal injury and/or property damage is possible if something is caught between the actuator stem and other control valve assembly parts.

Also, provide a certified pressure gauge suitable to accurately read the diaphragm pressure from 0 through 0.3 bar (5 psig) above the upper operating range pressure marked on the nameplate. Apply loading pressure to the diaphragm.

CAUTION

Stroke the actuator a few times to ensure that the pressure gauge is working correctly, and that the actuator is functioning properly. To prevent actuator damage, it is important to ensure that the actuator stem is stroking smoothly and not exhibiting binding or excessive friction. Binding or excessive friction could be an indicator of incorrect assembly or damaged parts.

1. If not already accomplished, provide a temporary means of applying an adjustable loading pressure to the actuator during bench set adjustments.
2. Set the diaphragm loading pressure at 0 bar (0 psig). Then, slowly raise the pressure towards the lower bench set pressure, as indicated on the nameplate, while checking for the first linear movement of the actuator stem. The actuator stem should show movement at the lower bench set pressure. If movement occurs before or after the lower pressure is reached, adjust the spring adjuster (see figure 4) into or out of the yoke until the actuator stem's movement is first detected at the lower bench set pressure.

Note

Before turning the spring adjuster on size 70/70i or 87 actuators, assemble the stem connector around the actuator stem and the anti-rotating lug on the yoke. Mark the actuator stem as a visual reference to verify that stem rotation does not occur. Remove the stem connector before rechecking the bench set.

3. Be sure the spring adjuster is adjusted to meet the requirements of step 2 above.
4. Apply the upper bench set pressure, as indicated on the nameplate. This pressure extends the actuator stem down towards the valve. At the end of the actuator stem, use a marker or a piece of tape to mark the valve stem (see figure 4).

Note

The actuator stem may slide over the valve stem as shown in figure 4. If the actuator stem does not pass over the valve stem, provide a method to mark this point of stem travel.

5. Slowly decrease the diaphragm loading pressure to the lower bench set pressure, as indicated on the nameplate.
6. Measure the distance between the marker or tape on the valve stem to the end of the actuator stem. The distance should match the rated travel indicated on the nameplate.
7. If the measured travel matches the nameplate travel, bench set is complete. Proceed to the Installing the Stem Connector Assembly subsection.
8. If the measured travel is not exact, consider the spring free-length and spring rate tolerances may produce a slightly different bench set than specified. Contact your [Emerson sales office](#) or Local Business Partner for assistance.

Installing the Stem Connector Assembly

When installing the stem connector assembly (key 26), the actuator and valve stem threads should engage the threads of the stem connector by the distance equal to the diameter of the stem.

⚠ WARNING

Install the stem connector securely before a positioner is mounted to the actuator and pressurized, using only a regulator-controlled air supply, not the positioner, to move the actuator stem.

To avoid personal injury or property damage, keep hands and tools out of the actuator stem travel path while applying loading pressure to move the actuator stem in the following steps.

CAUTION

To avoid damaging the seating surfaces, do not rotate the valve plug while it is seated. Exercise care while installing the stem connector assembly to avoid damage to the valve plug stem and valve stem threads.

Note

Replacement stem connectors are an assembly of two stem connector halves, cap screws, and a spacer between the connector halves. Remove the spacer and discard, if present, before clamping the actuator and valve stems together. Use only a mated pair of stem connector halves.

1. If necessary, push the valve stem down so that it is touching the seat ring on direct acting valves. For reverse acting valves, push the stem down to the open position.

If necessary, screw the valve stem locknuts down, away from the connector location. For all actuators except size 87, ensure that the travel indicator disk (key 14) is located on top of the locknuts.

2. Slowly increase the diaphragm pressure to the upper bench set pressure. This should be the same pressure used in the Spring Verification steps, and it is marked on the nameplate.
3. Place the stem connector half with the threaded holes, approximately half way between the actuator and valve stems, and align with the stem connector. A slight change to loading pressure may be necessary to align the threads. Refer to figures 6, 7, 8, 9, and 10 to help locate the connector position.

CAUTION

Incomplete engagement of either the valve stem or actuator stem in the stem connector can result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than one diameter of that stem. Damage to threads on either stem or in the stem connector can cause the parts to be replaced prematurely. Do not loosen the cap screws when the stem connector has spring or loading pressure force applied.

4. Install the other half of the stem connector and insert the cap screws and tighten them while ensuring even spacing between the stem connector halves on all sides. If installing a positioner, also attach the feedback bracket at the same time.

CAUTION

Over-tightening the valve stem locknuts can make disassembly difficult.

5. Screw the valve stem locknuts up against the stem connector for the size 87 actuator. For all other actuator sizes, screw the valve stem locknuts up until the indicator disk contacts the bottom of the stem connector. Do not overtighten the locknuts.
6. Slowly stroke the valve from fully open to fully closed and verify full rated travel is achieved.

Be sure that the valve is in the closed position. Loosen the screws on the travel indicator scale (key 18), and align it with the travel indicator disk (key 14) or stem connector for the size 87 actuator. Stroke the valve full travel to ensure that the travel matches the rated travel on the nameplate. If valve travel is not correct, repeat the stem connector procedure.

Friction Discussion

If you are attempting to adjust the bench set after the actuator is connected to the valve and the packing tightened, you must take friction into account. Make the spring adjustment so full actuator travel occurs at the bench set values (a) plus the friction force divided by the effective diaphragm area with increasing diaphragm pressure or (b) minus the friction force divided by the effective diaphragm area with decreasing diaphragm pressure.

If the stem connector assembly has been installed, the valve friction may be determined by the following procedure:

1. Install a pressure gauge in the actuator loading pressure line that connects to the actuator diaphragm casing.

Note

Steps 2 and 4 require that you read and record the pressure shown on the pressure gauge.

2. Increase the actuator diaphragm pressure and read the diaphragm pressure as the actuator reaches a travel position in the rated travel of the valve that does not contact a travel stop. Make a reference mark on the travel indicator scale using tape or some other method at this point.
3. Increase the actuator diaphragm pressure until the actuator is at a travel position greater than the position referenced in step 2 using the reference point to identify first movement.
4. Decrease the actuator diaphragm pressure and read the diaphragm pressure as the actuator returns to the position referenced in step 2.

The difference between the two diaphragm pressure readings is the change in the diaphragm pressure required to overcome the friction forces in the two directions of travel.

5. Calculate the actual friction force:

$$\text{Friction Force, = pounds} = 0.5 \left(\begin{array}{c} \text{Difference} \\ \text{in pressure} \\ \text{readings, psig} \end{array} \right) \times \left(\begin{array}{c} \text{Effective} \\ \text{diaphragm area,} \\ \text{inches}^2 \end{array} \right)$$

Refer to table 1 for the effective diaphragm area.

It is difficult to rotate the spring adjustor (key 74, figures 6, 7, 8, 9, and 10) when the full actuator loading pressure is applied to the actuator. Release the actuator loading pressure before adjusting. Then re-apply loading pressure to check the adjustment.

Note

For push-down-to-close valves, the valve plug seat is the limit for downward travel and the actuator up-stop is the limit for upward (away from the valve) movement. For push-down-to-open valves, the actuator down stop is the limit for downward movement, and the valve seat is the limit for upward (away from the valve) movement.

Deadband Measurement

Deadband is caused by packing friction, unbalanced forces, and other factors in the control valve assembly. Deadband is the range a measured signal can vary without initiating a response from the actuator (see figure 5). Each actuator spring has a fixed spring rate (force divided by compression). You have verified that the right spring was installed in the actuator by completing the Spring Verification steps.

Deadband is one factor that affects the control valve assembly operation during automatic loop control. The control loop tolerance for deadband varies widely depending on the loop response. Some common symptoms of the deadband being too wide are no movement, a “jump” movement, or oscillating movements of the actuator during automatic loop control. The following steps are provided to determine the span of deadband. The percent of deadband is helpful in troubleshooting problems with the process control loop.

1. Start at a pressure near the lower bench set pressure, slowly increase pressure until the valve is approximately at mid-travel. Note this pressure reading.
2. Slowly decrease pressure until movement of the valve stem is detected, and note this pressure.
3. The difference between these two pressures is deadband, in psi.
4. Calculate the percent of deadband by:

$$\text{Deadband} = \frac{\text{Deadband, psi}}{\text{Bench Set Span, psi}} = \text{nn\%}$$

Figure 5. Typical Valve Response to Deadband

NOTE:
 1 DEADBAND IS CAUSED BY FRICTION.
 A6763-2

Loading Connection

The loading pressure connections are made at the factory if the valve, actuator, and positioner come as a unit. Keep the length of tubing or piping as short as possible to avoid transmission lag in the control signal. If a volume booster, valve positioner or other accessory is used, be sure that it is properly connected to the actuator. Refer to the positioner instruction manual or other manuals as necessary.

For actuators shipped separately or whenever the actuator pressure connections are installed, use the following steps:

1. Connect the loading pressure piping to the NPT internal connection in the top of the diaphragm casing.
2. For sizes 70/70i and 87 actuators, if necessary, remove the 1/4 NPT bushing if a 1/2 NPT internal connection is needed to increase connection size. The connection can be made with either piping or tubing.
3. Cycle the actuator several times to be sure that the valve stem travel is correct when the correct pressure ranges are applied to the diaphragm.

⚠ WARNING

If valve stem travel appears to be incorrect, refer to the Bench Set Spring Adjustment procedures at the beginning of this section. To avoid personal injury or product damage, do not place the valve into service if it is not reacting correctly to diaphragm loading pressure changes.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced when necessary. The frequency of inspection and replacement depends on the severity of service conditions.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Actuator Maintenance

This procedure describes how the actuator can be completely disassembled and assembled. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job; then, start the assembly at the appropriate step.

Key numbers refer to figures 6, 7, 8, 9, or 10 unless otherwise indicated. Figure 6 shows the size 30 through 60 actuators, figure 7 shows the size 30i through 60i actuators, figure 8 illustrates the size 70 actuator, figure 9 illustrates the size 70i actuator, and figure 10 shows the size 87 actuator.

Actuator Disassembly

1. Bypass the control valve. Reduce the loading pressure to atmospheric, and remove the tubing or piping from the upper diaphragm casing (key 1).

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

657 Actuator (30/30i-70/70i and 87)

June 2018

Instruction Manual

D100306X012

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1) away from the actuator, relieve spring compression (step 2, below), and carefully remove casing cap screws (key 22) (step 4, below).

2. Thread the spring adjuster (key 12) out of the yoke (key 9) until all spring compression is relieved.
3. If required, remove the actuator from the valve body by separating the stem connector (key 26) and removing the yoke locknut or, for the size 87 actuator, the stud bolt nuts. Separate the stem connector by loosening the stem nuts (keys 15 and 16) and unscrewing the two cap screws.
4. Remove the diaphragm casing cap screws and nuts (keys 22 and 23), then lift off the upper diaphragm casing (key 1).
5. Remove the actuator diaphragm (key 2).
6. Remove the diaphragm plate, actuator stem, and cap screw (keys 4, 10 and 3) as an assembly. This assembly can be broken down further, if required, by removing the cap screw (key 3).
7. Remove the actuator spring (key 6) and the spring seat (key 11).
8. If required, remove the lower diaphragm casing (key 5) from the yoke (key 9) by loosening the cap screws (key 8) that hold it in place.
9. If required, remove the spring adjuster (key 12) by unscrewing it from the yoke (key 9).

1. Observe tightening pattern and procedure described in the appropriate Actuator Assembly section.

2. Torque values when lithium grease is used on the threads.

Actuator Assembly

Refer to table 2 as appropriate.

1. Coat the threads and the spring seat bearing surface of the spring adjuster (key 12) with lithium grease (key 241), and thread the spring adjuster into the yoke (key 9). Place the spring seat (key 11) in the yoke on the spring adjuster and turn the spring adjuster to ensure that threads are properly engaged.

2. Position the lower diaphragm casing (key 5) on the yoke (key 9), and fasten the parts together by installing and evenly tightening the cap screws (key 8).
3. Set the actuator spring (key 6) squarely onto the spring seat (key 11).
4. If the diaphragm plate and actuator stem (keys 4 and 10) are separate, fasten them together using the cap screw and washer (keys 3 and 25). Coat the cap screw threads with lithium grease (key 241). Tighten the cap screw (key 3) to 41 N•m (30 lbf•ft) torque for size 30/30i actuators, 54 N•m (40 lbf•ft) torque for size 34/34i and 40/40i actuators, or 149 N•m (110 lbf•ft) torque for size 45/45i to 87 actuators. Slide the actuator stem and diaphragm plate (keys 10 and 4) into the yoke (key 9) so that the actuator spring (key 6) fits squarely between the diaphragm plate and the spring seat (key 11). Then slide the diaphragm rod through the spring adjuster (key 12).

Note

Key 25 is not part of size 40 and 40i constructions.

5. Place the diaphragm (key 2) pattern-side up on the diaphragm plate (key 4). Align the holes in the diaphragm and the lower diaphragm casing (key 5).
6. Position the upper diaphragm casing (key 1) on the diaphragm (key 2) and align the holes.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 30/30i-70/70i and 87 actuators.

CAUTION

Over-tightening the diaphragm casing cap screws and nuts (keys 22 and 23) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

7. Insert the cap screws (key 22), and tighten the hex nuts (key 23) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to 13 N•m (10 lbf•ft).
8. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
9. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
10. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
11. After the last hex nut is tightened to 27 N•m (20 lbf•ft), all of the hex nuts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
12. Once completed, no more tightening is recommended.
13. Mount the actuator on the valve by following the procedures in the Installation section.

Top-Mounted Handwheel Assembly

A top-mounted handwheel assembly (figures 11 and 12) is usually used as an adjustable casing-mounted up travel stop to limit full retraction of the actuator stem. Turning the handwheel clockwise moves the the handwheel stem (key 133, figures 11 and 12) down, compressing the spring.

Instructions are given below for complete disassembly and assembly of the top-mounted handwheel assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Key numbers refer to figure 11 (sizes 30/30i through 60/60i) and figure 12 (sizes 70/70i and 87), unless otherwise indicated.

Disassembly for Top-Mounted Handwheel

1. Turn the handwheel (key 51) counter-clockwise so that the handwheel assembly is not causing any spring compression.
2. Bypass the control valve, reduce loading pressure to atmospheric, and remove the tubing or piping from the upper handjack body (key 142, figures 11 or 12).

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1) away from the actuator, thread the spring adjuster (key 12) out of the yoke until all spring compression is relieved, then carefully remove casing cap screws (key 22).

3. Remove the diaphragm casing cap screws and nuts (keys 22 and 23, figures 6, 7, 8, 9, or 10), and lift off the upper diaphragm casing and handwheel assembly.
4. If necessary, the handwheel assembly can be separated from the diaphragm casing by removing the cap screws (key 141). This may be necessary to replace the O-ring (key 139), or for ease of handling.
5. Loosen the travel stop locknut (key 137), and turn the handwheel (key 51) counter-clockwise. Remove the cotter pin and stop nut (keys 247 and 54), then lift off the handwheel.
6. Unscrew the travel stop locknut (key 137) from the handwheel stem (key 133), and turn the stem out of the bottom of the body (key 142). A screwdriver slot is provided on the top of the stem for this purpose.
7. Replace the O-ring (key 138) in the body (key 142).
8. For a handwheel assembly used on sizes 30/30i through 60/60i actuators, complete the disassembly by driving out the groove pin (key 140, figure 11) and sliding the pusher plate (key 135, figure 11) off the stem.

For a handwheel assembly used on a sizes 70/70i or 87 actuator, complete the disassembly by unscrewing the retaining screw (key 174, figure 12) and removing the thrust bearing and pusher plate (keys 175 and 135, figure 12). Because the retaining screw (key 174) has left-hand threads, turn clockwise to loosen.

Assembly for Top-Mounted Handwheel

1. For a handwheel assembly used on sizes 30/30i through 60/60i actuators, coat the end of the handwheel stem (key 133, figure 11) with anti-seize lubricant (key 244). Slide the pusher plate (key 135, figure 11), onto the stem, and drive in the groove pin (key 140, figure 11) to lock the pieces together.

For a handwheel assembly used on a sizes 70/70i or 87 actuator, pack the thrust bearing (key 175, figure 12) with anti-seize lubricant (key 244). Place the thrust bearing in the pusher plate (key 135, figure 12), slide the two parts onto the handwheel stem (key 133). Coat the retaining screw threads with thread locking sealant (key 242). Insert and tighten the retaining screw (key 174, figure 12).

2. Coat the O-ring (key 138) with lithium grease (key 241), and insert the O-ring in the body (key 142).
3. Coat the threads of the handwheel stem (key 133) with anti-seize lubricant (key 244). Screw the stem into the body (key 142).
4. Thread the travel stop locknut (key 137) onto the handwheel stem (key 133).

5. Place the handwheel (key 51), and the stop nut (key 54) on the handwheel stem (key 133). Tighten the hex nut to fasten the parts together. Secure the nut with the cotter pin (key 247).
6. If the body (key 142) was separated from the upper diaphragm casing (key 1, figures 6, 7, 8, 9, or 10), lubricate the O-ring (key 139) with lithium grease (key 241), and place the O-ring in the body. Align the holes in the diaphragm casing and the body, insert the cap screws (key 141), and tighten them evenly following a crisscross pattern to ensure a proper seal.
7. Position the upper diaphragm casing (key 1) on the diaphragm (key 2) and align the holes.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 30/30i-70/70i and 87 actuators.

CAUTION

Over-tightening the diaphragm casing cap screws and nuts (keys 22 and 23) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

8. Insert the cap screws (key 22), and tighten the hex nuts (key 23) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to 13 N•m (10 lbf•ft).
9. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
10. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
11. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
12. After the last hex nut is tightened to 27 N•m (20 lbf•ft), all of the hex nuts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
13. Once completed, no more tightening is recommended.
14. Mount the actuator on the valve following the procedures in the Installation section.

Side-Mounted Handwheel for Sizes 34 through 60 and 34i through 60i Actuators

A side-mounted handwheel assembly is normally used as a manual actuator for sizes 34 through 60 (figures 13 and 15) and 34i through 60i actuators (figures 14 and 16). Turning the handwheel counter-clockwise past the neutral position opens the valve. Two levers (key 146, figures 13, 14, 15, and 16) on a handwheel assembly operate the valve by moving the valve stem.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then begin the assembly at the appropriate step.

Disassembly for Side-Mounted Handwheel (Sizes 34-60 and 34i-60i)

1. Use step a. for size 34 through size 60 actuators, and use step b. for sizes 34i through 60i.
 - a. **For Size 34 through 60:** If desired, the handwheel assembly can be removed from the actuator yoke. To do this, remove the hex nuts (keys 147 and 170) from the U-bolts (key 166 and 143) that hold the assembly to the yoke for the size 30 and size 40. Remove the hex nuts (key 144 and 170) from the U-bolts (key 166 and 143) that hold the assembly to the yoke for the size 45 through size 60.
 - b. **For Size 34i through 60i:** If desired, the handwheel assembly can be removed from the actuator yoke. To do this, remove the cap screws (key 256 and 257) and spacers (key 258) that hold the assembly to the yoke for the size 30i through size 60i.
2. Remove the retaining ring (key 154) and drive out the lever pivot pin (key 153).
3. Two screws (key 156) hold the right- and left-hand levers (key 146) together. Remove the screw from the top of the levers so that the levers will drop down out of the assembly. Disassemble further, if necessary, by removing the other screw.
4. Remove the screw (key 161) and pointer mounting bolt (key 159, not shown) located behind the pointer (key 160).
5. Remove the stop nut (key 54), lockwasher (key 150), and washer (key 149). Then remove the handwheel (key 51), being careful not to lose the small ball (key 55) and spring (key 56).
6. Loosen the locking set screw (key 168, figure 16). Then, using a suitable tool, unscrew the bearing retainer (key 136).
7. Pull the handwheel screw assembly (key 145) out of the handwheel body. The operating nut (key 132) will come out with the screw. Also remove the bushing (key 151, figure 13 or 14) on size 34 and 40.
8. If required, remove the two ball bearings (key 152), one from the bearing retainer and the other from the handwheel body.

Assembly for Side-Mounted Handwheel (Sizes 34-60 and 34i-60i)

[Click here](#) or access the following QR code for a video on installing a side-mounted handwheel on a 657 actuator.

1. Pack the ball bearings (key 152) with anti-seize lubricant (key 244). Insert one bearing and the bushing (key 151, figure 13 or 14) into the handwheel body (key 142). The bushing is not used in a handwheel assembly for sizes 45/45i through 60/60i actuators.
2. Coat the handwheel screw assembly (key 145) threads with anti-seize lubricant (key 244), and thread the operating nut (key 132) onto the screw. Slide the second ball bearing (key 152) onto the screw, and insert the end of the screw into either the bushing (key 151, figure 13 or 14) for sizes 34/34i and 40/40i, or into the bearing for sizes 45/45i through 60/60i.
3. Thread the bearing retainer (key 136) into the body (key 142). Completely tighten the bearing retainer, and then loosen it one-quarter turn. Tighten the set screw (key 168, figure 13 or 14) to hold the bearing retainer in place.
4. Coat the groove in the handwheel body (key 142) with lithium grease (key 241). Insert the spring (key 56) and ball (key 55) into the handwheel (key 51). Holding the ball and spring in the handwheel, put the handwheel, the washer (key 149), the lockwasher (key 150), and the stop nut (key 54) onto the end of the end of the handwheel screw (key 145). Tighten the stop nut.
5. Position the pointer mounting bolt (key 159, not shown) and pointer (key 160). Insert and tighten the screw (key 161).
6. Assemble the two levers (key 146) with the cap screws (key 156) for handwheel assemblies for sizes 45/45i, 50/50i, and 60/60i actuators, or with the machine screws (key 156) for handwheel assemblies on sizes 34/34i and 40/40i actuators.

7. Use step a. for size 34 through size 60 actuators, and use step b. for sizes 34i through 60i.
 - a. **For Size 34 through 60:** If the handwheel assembly was removed from the yoke (key 9, figures 6, 8, or 10), remount the handjack assembly to the yoke using the dowel pins for alignment. For the size 34 and size 40, position the U-bolts and J-bolts (keys 166 and 143) on the yoke, and hand-tighten the hex nuts (keys 170 and 147) to hold the handwheel assembly in position. For the size 45 through size 60, position the U-bolts (keys 166 and 143) on the yoke, and hand-tighten the hex nuts (keys 170 and 144) to hold the handwheel assembly in position. Cap screws (key 163) should be tight against the yoke legs to provide stability. Tighten the nuts (key 144 for size 30 and size 40, key 158 for the size 45 through size 60). For the size 34 and size 40 finish tightening the U-bolt nuts to 81 N•m [60lbf•ft] (key 170) and 41 N•m [30 lbf•ft] (key 147). For the sizes 45 through 60 finish tightening the U-bolt nuts to 163 N•m [120lbf•ft] (key 170) and 41 N•m [30 lbf•ft] (key 144). Be sure the handwheel assembly remains flat against the mounting pad and perpendicular to the yoke.
 - b. **For Size 34i through 60i:** If the handwheel assembly was removed from the yoke (key 9, figures 7, 9, or 10), remount the handjack assembly to the yoke using the dowel pins for alignment. Position the upper cap screws (key 256) on the assembly and hand-tighten to hold the handwheel assembly in position. Place the spacers (key 258) between the yoke and handjack assembly, position cap screws (key 257), and hand-tighten. For the size 34i and size 40i, finish tightening the cap screws (key 256) to 81 N•m [60 lbf•ft] and (key 257) to 41 N•m [30 lbf•ft]. For the sizes 45i through 60i, finish tightening the cap screws (key 256) to 163 N•m [120 lbf•ft] and (key 257) to 41 N•m [30 lbf•ft].
8. Position the levers (key 146) as shown in figures 11 or 12. Insert the lever pivot pin (key 153), and snap the retaining ring (key 154) onto the lever pivot pin.

Side-Mounted Handwheel for Sizes 70 and 87 Actuators

A side-mounted handwheel assembly (figure 17) is normally used as a manual actuator for sizes 70 and 87 actuators. Turning the handwheel counter-clockwise past the neutral position opens the valve body. A pair of sleeves (keys 34 and 46, figure 17) operates the valve by moving the valve stem.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; and then begin the assembly at the appropriate step.

Key numbers refer to figures 8 or 10, and 13.

Disassembly for Side-Mounted Handwheel (Size 70 and 87)

1. Bypass the control valve, reduce loading pressure to atmospheric, and remove the tubing or piping from the upper diaphragm casing (key 1).
2. Remove cover band (key 60), and relieve spring compression by turning the spring adjuster (key 12) counter-clockwise.
3. Remove the cap screws and casing screws and nuts (keys 22 and 23), lift off the upper diaphragm casing (key 1), and remove the diaphragm (key 2).
4. Remove the cap screw (key 3) and the washer (key 25), then take off the diaphragm plate (key 4).
5. Remove the actuator spring (key 6), the upper sleeve (key 34), and the spring seat (key 11) from the yoke cylinder. This exposes the needle bearing and races (keys 37 and 38).
6. Separate the halves of the stem connector assembly (key 26) by removing the two cap screws. Remove the actuator stem (key 10).
7. Remove the travel indicator (key 14).

CAUTION

To avoid possible product damage, do not move the neutral indicator scale after completing the following step.

8. Turn the handwheel to raise the lower sleeve (key 46) until it is free of the worm gear (key 44). Lift out the lower sleeve and the key (key 47). Do not move the neutral indicator scale (key 59).
9. Loosen two set screws (key 40), then unscrew the bearing retainer flange (key 39) and the attached spring adjuster (key 12), using a suitable tool in the open neck of the flange. Take out the gear and two needle bearings (key 42), one on each side of the gear.
10. Remove the spring adjuster (key 12) from the bearing retainer flange (key 39). If desired, the worm shaft (key 45) and associated parts can be disassembled to replace or lubricate them. To do so, first remove the stop nut (key 54) and the handwheel (key 51). Do not lose the small ball (key 55) and spring (key 56).
11. Loosen the two set screws (key 41), and unscrew the front and back retainers (keys 48 and 49). The ball bearings (key 50) will come out with the retainers. Remove the worm shaft (key 45).

Assembly for Side-Mounted Handwheel (Size 70 and 87)

1. The front and back retainers (keys 48 and 49) each have a slot in their threads for a set screw (key 41). Pack the ball bearings (key 50) with anti-seize lubricant (key 244), and insert one ball bearing into the back retainer (key 49) as shown in figure 17.
2. Thread the back retainer and ball bearing (keys 49 and 50) into the yoke (key 9). Align the slot in the bearing retainer with the set screw hole in the yoke, insert the set screw (key 41), and tighten it.
3. Coat the worm shaft (key 45) threads with anti-seize lubricant (key 244), and slide the shaft into the yoke so that the end of the shaft fits snugly into the back retainer (key 49).
4. Insert the bearing into the front retainer (key 48), and thread the retainer and ball bearing into the yoke (key 9). Align the slot in the retainer with the hole in the yoke, insert the set screw (key 41), and tighten it.
5. Put the spring and ball (keys 56 and 55) into the handwheel (key 51). Slide the handwheel onto the worm shaft (key 45). Thread the stop nut (key 54) onto the shaft.
6. Pack the two needle bearings (key 42) and coat the worm gear (key 44) threads with anti-seize lubricant (key 244). Insert the key (key 47), the bearings, and the gear into the yoke (key 9) as shown in figure 17.
7. Slots are cut into the threads of the bearing retainer flange (key 39). Thread the flange into the yoke (key 9) so that the slots and the holes for the set screws (key 40) align. Insert the screws, and tighten them.
8. The lower sleeve (key 46) has milled slots in one end. Coat the sleeve threads with lithium grease (key 241), then slide the end of the lower sleeve with the milled slots into the bearing retainer flange (key 39).
9. Turn the handwheel (key 51), and feed the sleeve through the gear so that the slot in the lower sleeve (key 46) engages the key (key 47) in the yoke (key 9). Continue turning the handwheel until the lower sleeve protrudes 93.7 mm (3.69 inches) below the surface of the yoke. The pin in the side of the lower sleeve should line up with the extension on the neutral indicator.
10. Slide the square end of the actuator stem (key 10) through the lower sleeve (key 46) so the stem contacts the valve stem. Clamp both stems in the two halves of the stem connector (key 26). The stem connector should not be closer than 3.2 mm (1/8 inches) to the lower sleeve when the actuator stem is in the retracted position. This adjustment will provide approximately 3.2 mm (1/8 inches) of free travel of the lower sleeve in either direction for manual operation. Fasten the stem connector halves together with the cap screws.
11. Pack the needle bearing and race (keys 37 and 38) with lithium grease (key 241), and slide the bearing onto the spring adjuster (key 12).
12. Put the spring seat and actuator spring (keys 11 and 6) into the yoke (key 9). Slide the upper sleeve (key 34) onto the actuator stem (key 10).
13. Put the diaphragm plate and washer (keys 4 and 25) onto the actuator stem (key 10). Insert and tighten the cap screw (key 3) to fasten the parts together.
14. Place the diaphragm (key 2) pattern-side up onto the diaphragm plate (key 4). Align the holes in the diaphragm and the lower diaphragm casing (key 5).

15. Position the upper diaphragm casing (key 1) onto the diaphragm (key 2) and align the holes.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 30-70, 30i-70i, and 87 actuators.

CAUTION

Over-tightening the diaphragm casing cap screws and nuts (keys 22 and 23) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

16. Insert the cap screws (key 22), and tighten the hex nuts (key 23) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to 13 N•m (10 lbf•ft).
17. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
18. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
19. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
20. After the last hex nut is tightened to 27 N•m (20 lbf•ft), all of the hex nuts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
21. Once completed, no more tightening is recommended.
22. Mount the actuator onto the valve, following the procedures in the Installation section.
23. Return the actuator to service after completing the Loading Connection procedure in the Installation section and the procedures in the Adjustments section.

Casing-Mounted Adjustable Travel Stops

Note

If repeated or daily manual operation is expected, the actuator should be equipped with a manual top-mounted or side-mounted handwheel. Refer to the Top-Mounted Handwheel and Side-Mounted Handwheel sections of this instruction manual.

The casing-mounted adjustable up travel stop (figures 18 or 19) limits the actuator stroke in the upward direction. To adjust, first relieve actuator loading pressure before removing the travel stop cap (key 187, figure 18 or 19). Loosen the travel stop nut (key 137). Then turn the travel stop stem (key 133) clockwise into the diaphragm case to move the actuator stem downward (or counter-clockwise to move the stem upward). Finally, tighten the travel stop nut and replace the travel stop cap.

The adjustable down travel stop (figure 20) limits the actuator stroke in the downward direction. To adjust, first relieve actuator loading pressure before removing the travel stop cap (key 187). Then loosen the jam nut and adjust the stop nut (keys 189 and 54) either down on the stem to limit travel, or up on the stem to allow more travel. Lock the jam nut against the stop nut, then replace the closing cap.

Instructions are given below for disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Key numbers are shown in figures 18, 19, and 20.

Disassembly for Casing-Mounted Travel Stop

Bypass the control valve. Reduce the loading pressure to atmospheric, and remove the tubing or piping from the connection in the body (key 142).

Casing-Mounted Adjustable Up Travel Stops

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1) away from the actuator, relieve spring compression (steps 1 and 2, below), and carefully remove casing cap screws (key 22) (step 3, below).

1. Thread the spring adjuster (key 12) out of the yoke (key 9) until all spring compression is relieved.
2. Remove the travel stop cap (key 187) and loosen the travel stop nut (key 137). Rotate the travel stop stem (key 133) counter-clockwise until the travel stop assembly is no longer compressing the spring.
3. Remove the upper diaphragm casing (key 1, figures 6, 7, 8, 9, or 10) as outlined in the Maintenance section.
4. Remove the cap screws (keys 141) and separate the travel stop assembly from the upper casing.
5. Remove and inspect the O-rings (keys 138 and 139); replace if necessary.
6. Proceed with the following procedure, based on actuator size:
 - For sizes 30/30i through 60/60i, drive out the groove pin (key 140), and slide the pusher plate (key 135) off the travel stop stem (key 133).
 - For sizes 70/70i and 87, remove the retaining screw (key 174) to inspect the thrust bearing (key 175).

Casing-Mounted Adjustable Down Travel Stops

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1) away from the actuator, relieve spring compression (steps 1 and 2, below), and carefully remove casing cap screws (key 22) (step 3, below).

1. Thread the spring adjuster (key 12) out of the yoke (key 9) until all spring compression is relieved.
2. Remove the travel stop cap (key 187). Unscrew the jam nut and stop nut (keys 189 and 54) until the travel stop assembly is no longer compressing the spring. Remove the jam nut and stop nut.
3. Remove the upper diaphragm casing (key 1, figures 6, 7, 8, 9, or 10) as outlined in the Maintenance section.
4. Remove the cap screws (keys 141) and separate the travel stop assembly from the upper casing.

5. Remove and inspect the O-ring (keys 139); replace if necessary.
6. For all actuator sizes: Loosen the stop nut (key 54), then unscrew the travel stop stem (key 133) out of the actuator stem. The lower diaphragm plate can now be removed.

Assembly for Casing-Mounted Travel Stop

1. Reassemble the up or down travel stop in the reverse order of the disassembly steps, being sure to apply lubricant as shown by the lubrication boxes (key 241) in figures 6, 7, 8, 9, 10, 18, 19, or 20, as appropriate.
2. Readjust the travel stop to obtain the appropriate restriction by following the adjustment procedures presented in the introductory portion of the Casing-Mounted Adjustable Travel Stops section. Return the unit to operation.

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always mention this number when corresponding with your [Emerson sales office](#) or Local Business Partner regarding technical information or replacement parts. Also, reference the complete 11-character part number of each needed part as found in the following Parts List.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts Kits

Kits for Side-Mounted Handwheels

Retrofit kit includes parts to add a side-mounted handwheel.

Description	Part Number
Size 34 push down to close	30A8778X0A2
Size 34 push down to open	30A8778X0B2
Size 40 push down to close	30A8778X0C2
Size 40 push down to open	30A8778X0D2
Size 45 & 46 push down to close	40A8779X0A2

Introduction

Scope of Manual

This instruction manual provides information on installation, adjustment, maintenance, and parts ordering for the Fisher 657 actuator in sizes 80 and 100. Refer to separate instruction manuals for information about other equipment and accessories used with these actuators.

Do not install, operate, or maintain 657 actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

657 Size 80 and 100 Actuators

1. Heavy actuator-to-bonnet bolting.

2. This maximum casing pressure is not to be used for normal operating pressure.

Figure 2. Schematic Representation of Fisher 657 Actuator

AF3833-A
A0792-2

Description

The 657 actuator (figure 1) is a direct-acting, spring-opposed diaphragm actuator used for automatic operation of control valves. The actuator positions the valve plug in response to varying pneumatic loading pressure on the diaphragm. Figure 2 shows the operation of these actuators.

A 657 actuator can be furnished with either a top-mounted or side-mounted (size 80 only) handwheel assembly. A top-mounted handwheel assembly is normally used as an adjustable-up travel stop. The size 100 top-mounted

handwheel may be used as an auxiliary manual actuator. A side-mounted handwheel assembly is normally used as an auxiliary manual actuator.

Specifications

Refer to table 1 for specifications of the 657 actuator. See the actuator nameplate for information about a specific actuator.

Maximum Pressure Limitations

The casing and diaphragm of 657 actuators are pressure operated. The air pressure provides force to compress the spring and stroke the actuator. The following explanations describe the maximum pressure limitation for 657 actuators. Refer to the nameplate, warning tag, and table 1 for maximum values.

- **Maximum Casing Pressure for Actuator Sizing:** This is defined as the maximum pressure that can be applied to stroke the actuator, overcome unbalance forces, and provide seat load.
- **Maximum Diaphragm Casing Pressure:** If the maximum diaphragm casing pressure is exceeded, damage to the diaphragm, casing, or actuator may result. This pressure is not to be used for normal operating pressure.

WARNING

To avoid personal injury or parts damage, do not exceed the Maximum Diaphragm Casing Pressure listed in table 1. The Maximum Diaphragm Casing Pressure must not produce a force on the actuator stem greater than the maximum allowable actuator output thrust or the maximum allowable stem load.

Installation

WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

When an actuator and valve body are shipped together, the actuator is normally mounted on the valve. Follow the valve body instructions when installing the control valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the Actuator Mounting procedures as described below.

For information on mounting valve positioners, refer to the appropriate valve positioner instruction manual.

Actuator Mounting

1. To permit adjustment of the actuator spring, the size 100 actuator must be installed in a vertical position above the valve body. Mount the actuator on the valve bonnet. Insert the cap screws, and tighten the hex nuts, securing the actuator to the bonnet.

2. Screw valve stem locknuts (key 16, figure 4) all the way onto valve stem thread.
3. Connect an air supply to the diaphragm casing.
4. For push-down-to-close valves, be sure the valve plug is on its seat. Apply pressure to ensure that the actuator stem is fully extended. Reduce actuator loading pressure to retract the stem approximately 3.2 mm (1/8-inch).
5. For push-down-to-open valves, move valve plug to closed position. On large body sizes, this may require the use of a pry bar inserted through the body line opening. If the body is installed in a pipeline, the bottom flange (if one is used) can be removed and the valve plug pushed to the seat from the bottom opening. Pressure the actuator to move the stem out 3.2 mm (1/8-inch).

⚠ WARNING

To avoid personal injury due to the sudden uncontrolled movement of parts, do not loosen the stem connector cap screws when the stem connector has spring or loading pressure force applied to it.

CAUTION

Incomplete engagement of both valve stem and actuator stem in the stem connector can result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than the diameter of that stem.

6. Clamp the actuator and valve plug stems between the two stem connector halves (key 26, figure 4). Insert and tighten the stem connector cap screws.
7. Thread the stem locknuts against the stem connector.
8. Align the travel indicator scale (key 18, figures 4 and 5) to show valve position.

Loading Connection

1. Connect the loading pressure piping to the connection in the top of the diaphragm casing.
2. Remove the 1/4-inch bushing (key 33, figure 4 and key 120, figure 5) to increase connection size, if necessary. The connection can be made with either piping or tubing.
3. Keep the length of tubing or piping as short as possible to avoid transmission lag in the control signal. If an accessory (such as a volume booster or valve positioner) is used, be sure that the accessory is properly connected to the actuator. Refer to the positioner instruction manual as necessary.
4. Cycle the actuator several times to check that the valve stem travel is correct and that the travel occurs when the correct pressure range is applied to the diaphragm.
5. If valve stem travel is incorrect, refer to the Travel procedure in the Adjustments section.
6. If the pressure range is incorrect, refer to the Spring procedure in the Adjustments section.

Adjustments

Travel

Make travel adjustments when the motion observed during actuator travel is different from the travel stamped on the actuator nameplate. If the Actuator Mounting procedure was followed correctly, this adjustment should not be necessary.

When adjusting travel of a reverse-acting (push-down-to-open) valve, apply a slight pressure on the actuator diaphragm. This moves the valve plug off the seat, reducing the chance of damaging the valve plug or seat during adjustments.

1. Back the stem locknuts away from the stem connector, and slightly loosen the stem connector cap screws.

CAUTION

Do not use wrenches or other tools directly on the valve stem. Damage to the stem surface and subsequent damage to the valve packing may result.

2. Tighten the locknuts together, using a wrench, then screw the valve stem either into the stem connector to lengthen travel or out of the stem connector to shorten travel.
3. Cycle the actuator to check the travel. If actual travel is not equal to the specified travel, adjust and check travel until correct. Tighten the stem connector cap screws when correct travel is obtained.
4. Raise the travel indicator disk by threading the stem locknuts against the stem connector.

Spring

Make spring adjustments when the loading pressure range applied to achieve specified travel is not equal to the pressure range stamped on the actuator nameplate. Refer to the Bench Set pressure range on the nameplate when the valve contains no pressure and the packing is loosely inserted in the bonnet. Refer to the Max. Allow. Supply on the nameplate when the valve is controlling the specified pressure drop and the packing is tightened to stop leaks around the stem.

Monitor loading pressure carefully when making adjustments. Do not exceed the pressure specifications of either the loading regulator or the actuator casings.

Each actuator spring has a fixed pressure span. Changing the spring compression shifts the span up or down to make valve travel coincide with the loading pressure range.

Size 80

Remove cover band (key 60, figure 4), insert a rod of approximately 12.7 mm (1/2-inch) diameter into a hole in the adjusting screw (key 12, figure 4), and rotate the adjusting screw with the rod. Rotating the screw from left to right will increase the loading pressure required to start actuator stem travel; opposite rotation will decrease the pressure required to start travel.

Size 100

CAUTION

The actuator must be in the vertical position when adjusting spring to avoid damage to thrust bearing (key 35, figure 5) and to properly position spacers required for adjustment.

Remove the shroud plate (key 107, figure 5), and loosen the jam nut (key 115, figure 5).

Figure 3. Dimension B for Spring Adjustment

For small spring forces, adjustments can be made by rotating the adjusting nut (key 114, figure 5). Clockwise rotation (when viewed from diaphragm casings) of the adjusting nut will increase the loading pressure required to start actuator stem travel, and counterclockwise rotation will decrease the pressure required to start travel. Tighten the jam nut when adjustment is complete.

For high spring forces, it is necessary to use spacers between the lower diaphragm casing and the spring seat to isolate spring force from the adjusting nut.

⚠ WARNING

To avoid personal injury from the compressed actuator spring snapping back to its original length, make and use the spacers by following the instructions in the steps below.

To avoid personal injury, keep hands and tools away from the spring and spring seat as instructed in the following procedure.

1. It is recommended that three spacers be made of 3-inch schedule 80 pipe cut to the appropriate length specified in step 2. If other than the recommended material is to be used, be certain that the spacers are capable of withstanding the spring force involved. The spacers must be of equal length with ends cut squarely.
2. Measure dimension B as shown in figure 3. Cut length of spacers as follows:
 - a. If it is desired to decrease spring compression, make the spacers approximately 4.8 mm (3/16-inch) longer than dimension B.
 - b. If it is desired to increase spring compression, make the spacers approximately 4.8 mm (3/16-inch) shorter than either dimension B plus the amount of adjustment required or dimension B plus valve travel, whichever is less.
3. Whenever the total amount of adjustment required is greater than valve travel, the adjustment must be made in two or more steps, and the amount of adjustment taken in each step must be less than valve travel.
4. Pressure the actuator to attain full travel. Cautiously insert the spacers at equal intervals around the spring seat (key 11, figure 5). The spacers must be seated squarely when in use or they may slip out of position. Keeping hands and

tools away from the spring and spring seat, slowly decrease loading pressure until the spring force holds the spacers firmly between the spring seat and lower diaphragm casing (key 5, figure 5).

5. Loosen the jam nut. The adjusting nut can now be rotated clockwise (when viewed from the diaphragm casings) to increase the loading pressure required to start actuator stem travel or counterclockwise to decrease the pressure required to start travel.
6. Pressure the actuator to move the spring seat away from the spacers, and carefully remove the spacers.
7. If the total adjustment required was greater than valve travel, repeat the procedure. It will be necessary to make new spacers using the new dimension B and the remaining adjustment required or valve travel, whichever is less. Tighten the jam nut when adjustment is complete.

Maintenance

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

The maintenance instructions are divided into four sections: actuator (sizes 80 and 100); side-mounted handwheel assembly (manual operator); hydraulic snubber; and top-mounted handwheel assembly (adjustable-up travel stop).

Actuator

This procedure describes how the actuator can be completely disassembled and assembled. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job; then, start the assembly at the appropriate step.

Key numbers refer to figure 4 for size 80 actuators and figure 5 for size 100 actuators.

Size 80 Disassembly

1. Bypass the control valve. Reduce the loading pressure to atmospheric, and remove the tubing or piping from the top of the diaphragm casing (key 1).

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1) away from the actuator, relieve spring compression (step 2, below), and carefully remove casing cap screws (key 22) (step 4, below).

2. Remove cover band (key 60). Insert a rod of approximately 12.7 mm (1/2-inch) diameter into a hole in the adjusting screw (key 12), and rotate the adjusting screw from right to left until spring compression is relieved. If the actuator has a handwheel, rotate it counterclockwise, relieving all spring compression.
3. If necessary, the entire actuator may be removed from the valve body by unscrewing two cap screws from stem connector (key 26) and removing actuator-to-bonnet bolting.
4. Unscrew diaphragm casing cap screws and nuts (keys 22 and 23), and lift off upper diaphragm casing (key 1).
5. Remove the molded diaphragm (key 2).
6. For actuators without snubber, remove diaphragm plate and stem (keys 4 and 10) as an assembly. This assembly can be broken down further, if necessary, by removing the cap screw (key 3).
7. For actuators with snubber (see figure 7), unscrew cap screw (key 3), and remove diaphragm plate (key 4). Remove stem connector (key 26). Unscrew cap screws (key 85), and remove cylinder assembly (key 74) and attached stem and upper seat (keys 10 and 90) from actuator.

To disassemble snubber:

- a. Unscrew stem from piston/piston rod assembly (key 27).
- b. Remove retaining rings, cylinder heads, and piston/piston rod assembly (keys 76, 75, and 27). Replace packing and O-rings (keys 103, 104, 77 and 105) as required.
8. Remove actuator spring, upper sleeve, and spring seat (keys 6, 34 and 11).
9. Unscrew cap screws and nuts (keys 62 and 63), and remove spring case (key 29). Cap screws (key 62) on units with side-mounted handwheel do not use hex nuts (key 63).
10. For actuators without side-mounted handwheel, remove adjusting flange (key 36) and attached thrust bearing and adjusting screw (keys 35 and 12).
11. For actuators with side-mounted handwheel (see figure 7), unscrew cap screws (key 64), and remove adjusting flange (key 36) and attached thrust bearing and adjusting screw (keys 35 and 12). Do not lose the key (key 47).

Size 80 Assembly

1. Coat the threads of the adjusting flange (key 36) with anti-seize lubricant (key 244). Replace the adjusting flange, adjusting screw, and thrust bearing (keys 36, 12, and 35). Pack bearing with lithium grease lubricant (key 241).

For actuators with side-mounted handwheel, install the key (key 47) on the adjusting flange (key 36). Coat the adjusting flange threads with anti-seize lubricant. Install the adjusting flange so that the key engages the slot in the lower sleeve. Secure adjusting flange with cap screws (key 64). Adjust set screws (key 40, figure 7) to eliminate free play in handwheel bearings.

Note

Over-tightening the set screws will make handwheel operation difficult.

2. Mount the spring case (key 29) to the yoke (key 9) using cap screws and hex nuts (keys 62 and 63).

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

Instruction Manual

D100307X012

657 Size 80 and 100 Actuators

June 2017

3. Position the lower spring seat (key 11), and slide the actuator spring (key 6) squarely onto the spring seat.
4. If the diaphragm plate and actuator stem (keys 4 and 10) were separated, fasten them together using the cap screw (key 3) and tighten to a torque of 544 N•m (400 lbf•ft).

For actuators without a hydraulic snubber, slide upper sleeve (key 34) onto the actuator stem, and then slide upper sleeve, actuator stem and diaphragm plate into the spring case (key 29) so that the spring (key 6) fits squarely between the diaphragm plate and the spring seat (key 11).

For actuators with a snubber, thread the actuator stem and upper spring seat (keys 10 and 90) into the piston/piston rod assembly (key 27). Install the snubber assembly and attached actuator stem into the upper sleeve, spring case adaptor, and spring case (keys 34, 72, and 29). Secure with cap screws (key 85).

5. Place the diaphragm (key 2) with pattern side facing away from the diaphragm plate (key 4). Align the holes in the diaphragm and the lower diaphragm casing (key 5).
6. Position the upper diaphragm casing (key 1) on the diaphragm (key 2), and align the holes.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 80 and 100 actuators.

CAUTION

Over-tightening the diaphragm casing cap screws and nuts can damage the diaphragm. Do not exceed the following maximum torque values for the appropriate diaphragm material:

EPDM/Meta-Aramid: 95 N•m (70 lbf•ft) Nitrile, Silicone, FKM (fluorocarbon)/Meta-Aramid: 68 N•m (50 lbf•ft)

Table 2. Maximum Torque Values

DIAPHRAGM MATERIAL	INITIAL TORQUE N•m (lbf•ft)	FINAL TORQUE N•m (lbf•ft)
EPDM/Meta-Aramid	41 (30)	82, +/-13 (60, +/-10)
Nitrile, Silicone, FKM/Meta-Aramid	34 (25)	68 (50)

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

7. Insert the cap screws (key 22) into the diaphragm casing, and tighten the hex nuts (key 23) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to the initial torque value found in table 2 for the diaphragm material being used.
8. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to the initial torque value found in table 2 for the diaphragm material being used.
9. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to the final torque value that is specified in table 2 for the diaphragm material being used.

10. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to the final torque value that is specified in table 2 for the diaphragm material being used.
11. After the last hex nut is tightened complete another tightening sequence, this time in a circular pattern around the bolt circle to the final torque value that is specified in table 2 for the diaphragm material being used.
12. Once completed, no more tightening is recommended.
13. Mount the actuator on the valve in accordance with the procedures in the Installation section.

Size 100 Disassembly

Key numbers used in the following procedure are shown in figure 5 except when indicated.

Note

Two construction variations of the size 100 are based on spring length. Group 1 springs have a free length of 845 mm (33-1/4 inches), and group 2 springs have a free length of 419 mm (16-1/2 inches).

WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1) away from the actuator, relieve spring compression (step 1, below), and carefully remove casing cap screws (key 22) (step 7, below).

1. Remove shroud plate (key 107), loosen jam nut (key 115), and rotate adjusting nut (key 114) until spring compression is relieved.

Note

To relieve spring compression when high spring forces exist, refer to the Adjusting Actuator Spring section, and follow the instructions given for size 100 actuators with high spring forces.

2. Remove the pressure tubing or piping from the top of the diaphragm casing.
3. For actuators with top-mounted handwheel, rotate handwheel (key 51, figure 8) counterclockwise as far as it will go, unscrew cap screws (key 109, figure 5), and remove handwheel and gear case assembly (key 65, figure 8).
4. For actuators without top-mounted handwheel, unscrew cap screws (key 109), and remove diaphragm casing cover (key 123).
5. If necessary, remove the actuator from the valve body by separating the stem connector (key 26) and removing the actuator-to-bonnet bolting. Separate the stem connector by loosening the stem locknuts (key 16) and unscrewing the four cap screws.
6. Unscrew and remove actuator stem extension (key 116).
7. Unscrew cap screws (key 22), and remove upper diaphragm casing (key 1).
8. Remove backup plate, diaphragm retainer, diaphragm, diaphragm plate, and washer (keys 13, 110, 2, 4, and 117).
9. Unscrew the nuts that attach lower diaphragm casing (key 5) to actuator tie rods (key 21).
10. Remove lower diaphragm casing from tie rods and remove hex jam nut, adjusting nut thrust bearing (used with group 1 springs only), and spring seat (keys 115, 114, 35, and 11).

11. Remove seal bushing (key 111) and diaphragm casing cover O-rings (keys 112 and 113) from upper diaphragm casing (key 123). Replace with new parts if necessary. Apply lithium grease lubricant to the O-rings.
12. Remove actuator spring (key 6).

Size 100 Assembly

Note

Units using a group 2 spring require one spring seat (key 11) on each end of the spring (key 6); units using a group 1 spring require only one spring seat on the diaphragm end of the spring as shown in figure 5.

1. Place the spring and spring seats (keys 6 and 11) inside the spring case.
2. For actuators using a group 1 spring, pack the thrust bearing (key 35) with lithium grease lubricant (key 241). Place bearing on the spring seat.
3. Screw the hex jam nut and adjusting nut (keys 115 and 114) onto the actuator stem.
4. Install the lower diaphragm casing (key 5) on the actuator tie rods (key 21). Secure with hex nuts.

Note

Before installing diaphragm plate (key 4), rotate adjusting nut (key 114) until the top of the actuator stem is 264 mm (10-3/8 inches) above the inside surface of the lower casing (key 5).

When installing diaphragm (key 2), be certain that the rubber side of the diaphragm faces away from the spring.

CAUTION

To avoid product damage, smooth the edge of the diaphragm to avoid wrinkling, and be careful that the diaphragm fold does not get pinched when the upper casing (key 1) is installed.

5. Install washer, diaphragm plate, diaphragm, diaphragm retainer, and backup plate (keys 117, 4, 2, 110 and 13).
6. Apply lithium grease lubricant (key 241) to the thread on the diaphragm end of the actuator stem (key 10).
7. Position the upper diaphragm casing (key 1) on the diaphragm (key 2), and align the holes.

Note

If backup plate (key 13) interferes with installation of upper casing, rotate adjusting nut (key 114) to move the plate.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 80 and 100 actuators.

CAUTION

Over-tightening the diaphragm casing cap screws and nuts can damage the diaphragm. Do not exceed 68 N•m (50 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

8. Insert the cap screws (key 22), and tighten the hex nuts (key 23) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to 34 N•m (25 lbf•ft).
9. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 34 N•m (25 lbf•ft).
10. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to a torque of 68 N•m (50 lbf•ft).
11. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 68 N•m (50 lbf•ft).
12. After the last hex nut is tightened to 68 N•m (50 lbf•ft), all of the hex nuts should be tightened again to 68 N•m (50 lbf•ft) in a circular pattern around the bolt circle.
13. Once completed, no more tightening is recommended.
14. Install the actuator stem extension (key 116), diaphragm casing cover O-rings (keys 112 and 113), and seal bushing (key 111). Install the gear case cover (key 123) or the handwheel assembly (see figure 8).
15. Mount the actuator on the valve, and secure with the actuator-to-bonnet bolting. Refer to the Installation section to connect actuator stem to valve plug stem.

Size 80 Side-Mounted Handwheel

The side-mounted handwheel assembly (figure 7) is normally used as a manual operator. The handwheel can be mounted in either of two positions so that, regardless of valve plug action, counterclockwise rotation always opens the valve. The assembly is a continuously connected type with an indicator to show neutral position. By rotating handwheel away from neutral, the handwheel can be used to limit travel in either direction but not both directions at the same time.

A grease fitting is provided on the gear box for periodic gear lubrication with a general-purpose grease.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Key numbers refer to figure 7.

Disassembly

1. Complete steps 1 through 9 of the disassembly portion of the size 80 actuator section.
2. Unscrew cap screws (key 64), and remove adjusting flange (key 36). Do not lose the key (key 47).
3. Unscrew the two screws (key 28), and remove travel stop indicator (key 58) from lower sleeve (key 46).
4. Turn handwheel (key 51) to raise lower sleeve. Continue turning handwheel until lower sleeve is free of worm gear (key 44). Lift out lower sleeve, bearing and gear retainer, thrust bearings, and worm gear (keys 46, 66, 67, and 44).
5. The worm shaft (key 45) and associated parts can be removed in order to replace or lubricate them. First, remove the handwheel cap (key 54) and the handwheel (key 51). Do not lose the small ball or spring (keys 55 and 56).

6. Loosen the two set screws (key 41), and unscrew the two worm retainers (keys 48 and 49). The ball bearings (key 50) will come out with the retainers. Remove the worm shaft (key 45).

Assembly

1. Pack the ball bearings (key 50) with lithium grease lubricant, and insert one ball bearing in the back worm retainer (key 49) as shown in figure 7 (section C-C).
2. Thread the back worm retainer and ball bearing (keys 49 and 50) into the gear case. Align the slot in the worm retainer with the set screw hole in the gear case, insert the set screw (key 41), and tighten it.
3. Coat the worm shaft (key 45) threads with anti-seize lubricant (key 244), and slide the shaft into the gear case so that the end of the shaft fits snugly in the back worm retainer.
4. Insert the bearing in the front worm retainer (key 48), and thread the retainer and ball bearing into the gear case. Align the slot in the retainer with the set screw hole in the gear case, insert the set screw (key 41), and tighten it.
5. Put the spring and ball (keys 56 and 55) in the handwheel (key 51). Slide the handwheel onto the worm shaft (key 45). Thread the handwheel cap (key 54) onto the worm shaft.
6. Pack the two thrust bearings (key 67) with lithium grease lubricant. Install one thrust bearing; then, install the worm gear (key 44) followed by the second thrust bearing and the bearing and gear retainer (key 66).
7. The lower sleeve (key 46) has two screw holes in one end. Coat the sleeve threads with lithium grease lubricant, slide the end of the lower sleeve with the holes into the thrust bearing (key 67), turn the handwheel, and feed the sleeve through the worm gear. Continue turning the handwheel until the lower sleeve protrudes from the gear case. Fasten the travel stop indicator (key 58) to the sleeve with the two machine screws (key 28).
8. Install the key (key 47) on the adjusting flange (key 36). Coat the adjusting flange threads with anti-seize lubricant (key 244). Install the adjusting flange so that the key engages the slot in the lower sleeve. Secure adjusting flange with cap screws (key 64).
9. Adjust set screws (key 40) to eliminate free play in the bearings.

Note

Over-tightening the set screws will make handwheel operation difficult.

10. Install the adjusting screw and thrust bearings (keys 12 and 35). Pack bearings with lithium grease lubricant (key 241), and install as shown in figure 7.
11. Slide the spring case (key 29) into position, and secure with cap screws (key 62).
12. Complete steps 3 through 8 of the size 80 actuator assembly section.

Size 80 Hydraulic Snubber

The size 80 657 is available with a hydraulic snubber, as shown in figure 7, to dampen vertical instability of actuator stem movement. The snubber is adjusted by rotating the adjusting screws (key 83, figure 7) counterclockwise out of the reservoir (key 79, figure 7) to increase damping action and clockwise to decrease damping action. The adjusting screw on the right (the lower of the two adjusting screws in section B-B of figure 7) regulates downward damping action, and the screw on the left regulates upward damping action.

Size 80 Top-Mounted Handwheel (Adjustable Up Travel Stop)

CAUTION

If repeated or daily manual operation is expected, and the actuator is equipped with a casing-mounted travel stop or top-mounted handwheel, the diaphragm could be subject to excessive wear.

The actuator should be equipped with a side-mounted handwheel, which is designed for more frequent use as a manual operator.

A top-mounted handwheel assembly is normally used as an adjustable-up travel stop to limit full retraction of the actuator stem. Turning the handwheel clockwise turns the handwheel stem (key 133, figure 6) into the diaphragm casing and forces the pressure block assembly (key 179, figure 6) against the diaphragm and diaphragm plate. Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Key numbers refer to figure 4 for actuator parts and figure 6 for handwheel parts.

Disassembly

1. Bypass the control valve. Reduce the loading pressure to atmospheric, and remove the tubing or piping from the diaphragm casing (key 1).

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1) away from the actuator, relieve spring compression (step 2, below), and carefully remove casing cap screws (key 141) (step 3, below).

2. Remove cover band (key 60). Insert a rod of approximately 12.7 mm (1/2-inch) diameter into a hole in the adjusting screw (key 12), and rotate the adjusting screw from right to left until spring compression is relieved. Rotate handwheel to be sure it is not compressing actuator spring.
3. Unscrew cap screws (key 141), and remove handwheel assembly.
4. Remove hex nut (key 54), and lift off the handwheel.
5. Unscrew support screws (key 182), and remove pressure block, stem, stem collar, and thrust bearing (keys 179, 133, 183, and 175).
6. Unscrew body nut (key 186), and remove gland (key 180). If necessary, remove and replace packing rings (key 181).

Assembly

1. Install new packing rings and gland (keys 181 and 180), and thread the body nut (key 186) onto the body.
2. Lubricate the thrust bearing and stem (keys 175 and 133), with lithium grease lubricant (key 241). Slide stem, stem collar, thrust bearing, and pressure block (keys 133, 183, 175, and 179) into the body as shown in figure 6 and install support screws (key 182).
3. Install handwheel and hex nut (keys 51 and 54).
4. Install a new handwheel gasket (key 185).
5. Mount the handwheel assembly on the diaphragm casing, and secure with cap screws (key 141).
6. Reconnect pressure tubing or piping to actuator casing.

Size 100 Top-Mounted Handwheel (Adjustable Up Travel Stop)

A top-mounted handwheel assembly is normally used as an adjustable-up travel stop to limit full retraction of the actuator stem. Clockwise rotation of the handwheel (key 51) moves the actuator stem (key 10) downward, compressing the spring (key 6). Spring action returns the stem as the handwheel is turned counterclockwise. Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Key numbers refer to figure 5 for actuator parts and figure 8 for handwheel parts.

Disassembly

1. Bypass the control valve. Reduce the loading pressure to atmospheric (refer to the Maintenance section), and remove the tubing or piping from the diaphragm casing.

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1) away from the actuator, relieve spring compression (step 2, below), and carefully remove casing cap screws (key 124) (step 3, below).

2. Rotate handwheel counterclockwise, relieving all spring compression.
3. Unscrew cap screws (key 124), and remove gear case cover (key 123).
4. Loosen the set screws (key 41) in the front and back worm retainers (keys 48 and 49) and handwheel (key 51).
5. Remove retaining ring (key 118), and remove handwheel.
6. Remove front and back worm retainers (keys 48 and 49).
7. Remove worm shaft (key 45).
8. Pull the power screw assembly (key 122). The bearing and gear retainer, thrust bearing, and worm gear (keys 66, 67 and 44) will come out with the power screw.

Assembly

1. Pack the ball bearings (key 50) with lithium grease lubricant (key 241), and insert one ball bearing into the back worm retainer (key 49).
2. Thread the back worm retainer and ball bearing into the gear case. Align the slot in the worm retainer with the set screw hole in the gear case, insert set screw (key 41), and tighten.
3. Coat the worm shaft (key 45) threads with lithium grease lubricant, and slide the shaft into the gear case so that the end of the shaft fits snugly in the back worm retainer.
4. Insert the bearing into the front worm retainer (key 48), and thread the retainer and ball bearing into the gear case. Align the slot in the retainer with the hole in the gear case, insert the set screw (key 41), and tighten.
5. Slide the handwheel onto the worm shaft (key 45), and install retaining ring (key 118).
6. Pack the two thrust bearings (key 67) with lithium grease lubricant. Install one thrust bearing, then the worm gear (key 44), followed by the second thrust bearing and the bearing and gear retainer (key 66).
7. Coat the power screw threads (key 122) with lithium grease lubricant. Slide the power screw into the thrust bearing (key 67), turn the handwheel, and feed the sleeve through the worm gear.
8. Adjust set screws (key 40) to eliminate free play in the bearings.

Note

Over-tightening the set screws will make handwheel operation difficult.

9. Install gear case cover (key 123), and tighten cap screws (key 124).

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always refer to this number when corresponding with your [Emerson sales office](#) or Local Business Partner regarding replacement parts or technical information.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts List

Note

Contact your [Emerson sales office](#) or Local Business Partner for Part Ordering information.

Introduction

Scope of Manual

This manual provides installation, maintenance, and parts list information for the Fisher 657NS actuator. Refer to separate instruction manuals for information regarding the control valve and accessories.

Do not install, operate, or maintain 657NS actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

The 657NS actuator is a direct-acting, spring-opposed diaphragm actuator used for operation of automatic control valves. The 657NS actuator yoke construction and special yoke-to-bonnet bolting provides a high structural resonant frequency that exceeds most nuclear service seismic requirements.

Specifications

Tables 1, 2, and 3 provide specifications for the various sizes of 657NS actuators discussed in this instruction manual. Specific actuator information is found on the actuator yoke nameplate.

⚠ WARNING

To avoid personal injury or property damage, do not exceed pressure and temperature limits specified in table 1.

emerson.com/mytraining

Installation

The diaphragm actuator is normally shipped mounted on a valve body. Follow the valve body instructions when installing the control valve in the pipeline.

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

⚠ WARNING

If the control valve and actuator are installed with the actuator in any position other than vertical, the actuator may not conform with safety-related qualifications. Nonvertical orientation should be part of existing qualification analysis on file at the plant site to ensure conformance with safety-related qualifications.

The control valve assembly normally may be installed in any orientation; however, the assembly must not be installed so that water can collect in the actuator yoke and lower diaphragm casing areas.

Note

The 657NS actuator will not mount on a standard valve bonnet; it requires a style NS bonnet having eight bonnet-to-yoke stud bolts.

If the actuator and control valve body are separate, mount the 657NS actuator on the valve body by following the procedures in the Actuator Mounting section of this manual.

Actuator Mounting

Direct-Acting (Push-Down-to-Close) Valves

See figure 1.

1. Screw the stem locknuts all the way onto the valve stem. Put the travel indicator disk, not used with the size 80 actuator, on the stem locknuts. The concave side of the disk should face the valve.
2. Push the valve stem down to close the valve.
3. Lift or hoist the actuator onto the valve bonnet.
4. Insert the cap screws and tighten the hex nuts (not shown), securing the actuator to the bonnet. Tighten the cap screws to the torque shown in table 5.
5. Thread the spring adjuster (see figure 1 for sizes 40 through 70 and key 12, figure 4 for size 80) until the actuator is at the full up position.
6. With the travel indicator scale attached to the actuator yoke, make a temporary mark on the actuator stem at a point parallel with the top mark on the travel indicator scale. This is the fully open position.
7. Refer to the actuator nameplate to determine the bench set pressure range of the actuator. Apply the lower bench set pressure to the actuator, and turn the spring adjuster until the actuator stem mark is even with the top mark on the travel indicator scale.
8. Apply the higher bench set pressure to the actuator. Verify that the mark on the actuator stem is even with the bottom mark on the travel indicator scale. This is the fully closed position. The distance from the top mark on the scale to the bottom mark is equal to the travel of the valve.

If the marks are in line, the actuator is properly bench set.

If the marks are not in line, the spring is not correct for the specified bench set. It is necessary to use a different spring or a different bench set.

⚠ WARNING

To avoid personal injury due to the sudden uncontrolled movement of parts, do not loosen the cap screws when the stem connector has spring or loading pressure force applied to it.

NOTICE

Incomplete engagement of the valve stem and/or actuator stem in the stem connector can result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than the diameter of that stem.

Note

Replacement stem connectors are an assembly of two stem connector halves, cap screws, and a spacer between the connector halves. Remove the spacer, if present, before clamping the stems together.

9. Push the valve stem firmly against its seat, and be sure that it remains firmly against the seat. Clamp the actuator stem and valve stem between the two stem connector halves. If necessary, increase loading pressure slightly to allow the valve stem, actuator stem, and stem connector threads to match.

Insert and tighten the stem connector cap screws.

10. Raise the travel indicator disk to the stem connector (for sizes 40 through 70). For all sizes, thread the stem locknuts against the stem connector.
11. Remove all loading pressure. Move the travel indicator scale so that the indicator disk (or pointer) is in line with the top mark of the travel indicator scale.
12. Check the valve travel to be sure that the valve travels fully with no overtravel.

Reverse-Acting (Push-Down-to-Open) Valves

See figure 1.

1. Screw the stem locknuts all the way onto the valve stem. Put the travel indicator disk (not used with the size 80 actuator) on the stem locknuts. The concave side of the disk should face the valve.
2. Push the valve stem down to open the valve.
3. Lift or hoist the actuator onto the valve bonnet.
4. Insert the cap screws and tighten the hex nuts (not shown), securing the actuator to the bonnet. Tighten the cap screws to the torque shown in table 5.
5. Apply actuator loading pressure until the actuator is at the full down position.
6. With the travel indicator scale attached to the actuator yoke, make a temporary mark on the actuator stem at a point parallel with the bottom mark on the travel indicator scale. This is the fully open position.
7. Refer to the actuator nameplate to determine the bench set pressure range of the actuator. Apply the lower bench set pressure to the actuator. Turn the spring adjuster until the actuator stem mark is even with the top mark on the travel indicator scale.
8. Apply the higher bench set pressure to the actuator and verify that the mark on the actuator stem is even with the bottom mark on the travel indicator scale. This is the fully-open position. The distance from the top mark on the scale to the bottom mark is equal to the travel of the valve.

If the marks are in line, the actuator is properly bench set.

If the marks are not in line, the spring is not correct for the specified bench set. It is necessary to use a different spring or a different bench set.

⚠ WARNING

To avoid personal injury due to the sudden uncontrolled movement of parts, do not loosen the cap screws when the stem connector has spring or loading pressure force applied to it.

NOTICE

Incomplete engagement of the valve stem and/or actuator stem in the stem connector can result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than the diameter of that stem.

Note

Replacement stem connectors are an assembly of two stem connector halves, cap screws, and a spacer between the connector halves. Remove the spacer, if present, before clamping the stems together.

9. Reduce loading pressure until the temporary mark on the actuator stem is parallel with the top mark on the indicator scale.
10. Pull the valve stem firmly against its seat, and be sure that it remains firmly against the seat. Clamp the actuator stem and valve stem between the two stem connector halves. If necessary, increase loading pressure slightly to allow the valve stem, actuator stem, and stem connector threads to match.

Insert and tighten the stem connector cap screws.

11. Raise the travel indicator disk to the stem connector (sizes 40 through 70 only). For all sizes, thread the stem locknuts against the stem connector.
12. Remove all loading pressure. Move the travel indicator scale so that the indicator disk (or pointer) is in line with the top mark of the travel indicator scale.
13. Check the valve travel to be sure that the valve travels fully with no overtravel.

Loading Connection

1. Connect the loading pressure piping to the NPT internal connection in the top of the actuator yoke.
2. For size 70 actuators, remove the 1/4-inch bushing in the 1/2 NPT internal connection to increase connection size, if necessary. The connection can be made with either piping or tubing.
3. Keep the length of tubing or piping as short as possible to avoid transmission lag in the control signal. If a volume booster, valve positioner or other accessory is used, be sure that it is properly connected to the actuator. Refer to the positioner instruction manual as necessary.
4. Cycle the actuator several times to check that the valve stem travel is correct and that the travel occurs when the correct pressure range is applied to the diaphragm.
5. If valve stem travel is incorrect, refer to the Travel procedure in the Adjustments section.
6. If the pressure range is incorrect, refer to the Spring procedure in the Adjustments section.

Figure 1. Schematic and Stem Connection Details for Fisher 657NS

Adjustments

Travel

⚠ WARNING

When moving the actuator stem with diaphragm loading pressure, use caution to keep hands and tools out of the actuator stem travel path. Personal injury and/or property damage is possible if something is caught between the actuator stem and other control valve assembly parts.

Make travel adjustments when the motion observed during actuator travel is different from the travel stamped on the actuator nameplate. If the Actuator Mounting procedure was followed correctly, this adjustment should not be necessary.

When adjusting travel of a reverse-acting (push-down-to-open) valve, apply sufficient loading pressure to move the valve plug off of the seat. This procedure reduces the chance of damaging the valve plug or seat during adjustments.

1. Back the stem locknuts and travel indicator disk away from the stem connector, and slightly loosen the stem connector cap screws.

NOTICE

Do not use wrenches or other tools directly on the valve stem. Damage to the stem surface and subsequent damage to the valve packing might result.

2. Tighten the locknuts together using a wrench, then screw the valve stem either into the stem connector to lengthen travel or out of the stem connector to shorten travel.
3. Cycle the actuator to check the travel. If actual travel is not equal to the specified travel, adjust and check travel until correct. Tighten the stem connector cap screws when correct travel is obtained.
4. Raise the travel indicator disk by threading the stem locknuts against the stem connector.

Spring

Bench Set

The bench set pressure range is used to adjust the initial compression of the actuator spring with the actuator assembly “on the bench”. The correct initial compression ensures that the valve-actuator assembly will function properly when it is put in service and the proper actuator diaphragm operating pressure is applied.

The bench set range is established with the assumption that there is no packing friction. When attempting to adjust the spring in the field, it is very difficult to ensure that there is no friction being applied by “loose” packing.

Accurate adjustment to the bench set range can be made during the actuator mounting process (see the Actuator Mounting procedure) by making the adjustment before the actuator is connected to the valve.

If you are adjusting to the bench set range after the actuator is connected to the valve and the packing tightened, you must take friction into account. Make the spring adjustment such that full actuator travel occurs at the bench set range (a) plus the friction force divided by the effective diaphragm area with increasing diaphragm pressure or (b) minus the friction force divided by the effective diaphragm area with decreasing diaphragm pressure.

For an assembled valve-actuator assembly, determine valve friction as described below:

1. Install a pressure gauge in the supply pressure line that connects to the actuator diaphragm casing.
2. Increase the actuator diaphragm pressure. Record the diaphragm pressure as the actuator reaches its mid-travel position.
3. Increase the actuator diaphragm pressure until the actuator is at a travel position greater than its mid-travel position.
4. Decrease the actuator diaphragm pressure. Record the diaphragm pressure as the actuator reaches its mid-travel position.

The difference between the two diaphragm pressure readings is the change in the diaphragm pressure required to overcome the friction forces in the two directions of travel.

5. Calculate the actual friction force:

$$\text{Friction Force, pounds} = 1/2 \left(\begin{array}{c} \text{Difference} \\ \text{in pressure} \\ \text{readings, psig} \end{array} \right) \times \left(\begin{array}{c} \text{Effective} \\ \text{diaphragm area,} \\ \text{inches}^2 \end{array} \right)$$

Refer to table 1 and 3 for the effective diaphragm area.

When determining valve friction, you can make diaphragm pressure readings at a travel position other than mid-travel if you desire. If you take readings at the zero or at the full travel position, ensure that the readings are taken when the travel just begins or just stops at the position selected.

The spring adjustor is difficult to rotate. Release the loading pressure before adjusting, then re-apply loading pressure to check the adjustment.

Bench Set Adjustments

1. Monitor loading pressure carefully when making adjustments. Do not exceed the maximum pressure specifications of either the loading regulator or the actuator casings (refer to table 1 for Maximum Diaphragm Casing Pressure).
2. Each actuator spring has a fixed pressure span. Changing the spring compression shifts the span up or down to make valve travel coincide with the loading pressure range.
3. For sizes 40 through 70, turn the spring adjustor (key 12, figure 2 or 3) into the yoke to shift the span up or turn the spring adjustor out of the yoke to shift the span down. For size 80, remove the spring case assembly (key 35, figure 4) by removing the cap screws (key 6, figure 4). Then rotate the spring adjustor (key 12, figure 4) to shift the span. Replace the spring case assembly and screws.

If the actuator has a side-mounted handwheel assembly, turn the handwheel clockwise to close the valve.

For successful operation, the actuator stem and valve plug stem must move freely in response to the loading pressure change on the diaphragm.

Operation

In a direct-acting diaphragm actuator, an increasing loading pressure causes the actuator stem to move downward, compressing the spring. When the diaphragm pressure is decreased, the spring moves the actuator stem upward. This

is shown graphically in figure 1. In the event of failure of the loading pressure to the diaphragm of the actuator, the actuator stem moves to the extreme upward position. Thus, by the proper selection of the valve plug action, either push-down-to-close or push-down-to-open, the control valve will either close or open on failure of the loading pressure.

The nameplate attached to the yoke of the actuator provides information about the specific construction and operating range. The spring and diaphragm have been selected to meet the requirements of the application, and in service, the actuator should create full travel of the valve plug when the diaphragm pressure (operate) range indicated on the nameplate is applied. This diaphragm pressure range is generally 0.2 to 1.0 bar or 0.4 to 2.0 bar (3 to 15 psi or 6 to 30 psi).

Pressure in the valve body creates a force on the valve plug that has a direct effect on the actual operating diaphragm pressure range. In some instances, the valve may not stroke completely over the indicated range because the pressure conditions in the body are different from those for which the control valve has been set at the factory. A simple spring adjustment, however, may be all that is required to obtain correct travel for the diaphragm pressure range utilized. Note that the actuator spring has a fixed pressure span and that adjustment of the spring compression merely shifts this span up or down to make valve travel coincide with the diaphragm pressure range.

The nameplate specifies a bench set pressure range in addition to a diaphragm pressure (operate) range. The bench set range is that pressure range required to stroke the valve fully without any pressure in the body, as would be the case if the valve were set on the work bench. However, in service, with the specified pressure drop applied across the valve, it should stroke over the diaphragm pressure (operate) range indicated on the nameplate.

When the control valve and actuator are installed, the actuator should be checked for correct travel, freedom from excessive friction, and correct action (air-to-open or air-to-close) to match the controlling instrument. For successful operation, the actuator stem and the valve plug stem must move freely in response to the loading pressure change on the diaphragm.

Maintenance

Normally, only the elastomeric parts and the spring of the 657NS actuator require inspection or replacement. The maintenance instructions are divided into three subsections: Replacement of the Elastomeric Parts, Disassembly, and Assembly. Perform only those steps applicable to the actuator size and required maintenance.

All maintenance operations can be performed with the valve in the line.

It is recommended that the diaphragm and all of the other elastomeric parts of the 657NS actuator be inspected every two years. The absolute maximum replacement period for any of the elastomeric parts is four years.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.

- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Replacement of the Elastomeric Parts

Size 40, 45, and 70 Actuators

Perform the following if it is desired to replace only the elastomeric parts of the 657NS actuator, and no other maintenance is necessary. The diaphragm is the only elastomeric part in the size 40, 45, and 70 actuators. Key number references are shown in figure 2 for size 40 and 45 actuators and in figure 3 for size 70 actuators.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Reduce the actuator loading pressure to atmospheric pressure, and remove the tubing or piping from the top of the upper diaphragm casing (key 1).
2. Remove the diaphragm casing cap screws and nuts (keys 22 and 23), and lift off the upper diaphragm casing.
3. Take out the diaphragm (key 2), and install a new one.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing cap screws are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 40, 45, and 70 actuators.

NOTICE

Overtightening the diaphragm casing cap screws and nuts (keys 22 and 23) can damage the diaphragm. Do not exceed a torque of 27 N•m (20 lbf•ft) when performing this tightening procedure.

Note

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

4. Place the upper diaphragm casing (key 1) into position, and replace the diaphragm casing cap screws and nuts (keys 22 and 23). Tighten the hex nuts (key 23) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to 13 N•m (10 lbf•ft).
5. Tighten the remaining hex nuts in a clockwise, crisscross pattern to 13 N•m (10 lbf•ft).
6. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
7. Tighten the remaining hex nuts in a clockwise, crisscross pattern to 27 N•m (20 lbf•ft).

8. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
9. Once completed, no more tightening is recommended.
10. Replace the tubing or piping to the top of the upper diaphragm casing.

Size 80 Actuators

The elastomeric parts in a size 80 actuator include the diaphragm and O-rings. Since replacement of these parts necessitates complete disassembly, perform the steps outlined in Size 80 Actuators, disassembly and assembly procedures.

Disassembly

Size 40, 45, and 70 Actuators

Key number references are shown in figure 2 for size 40 and 45 actuators and in figure 3 for size 70 actuators.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Reduce the actuator loading pressure to atmospheric pressure, and remove the tubing or piping from the top of the upper diaphragm casing (key 1).
2. To aid in assembly, record the position of the spring adjusting screw (key 12) relative to the actuator yoke (key 9). Loosen the spring adjusting screw locking set screw (key 67), and thread the adjusting screw out of the yoke until all spring compression is relieved.
3. If necessary, remove the actuator from the valve body by separating the stem connector (key 26) and removing the eight bonnet stud bolt nuts. Separate the stem connector by loosening the stem hex nuts (keys 15 and 16) and unscrewing the two cap screws.
4. Remove the diaphragm casing cap screws and nuts (keys 22 and 23), and lift off the upper diaphragm casing (key 1).
5. Take out the molded diaphragm (key 2).
6. The diaphragm plate and actuator stem (keys 4 and 10) can be taken out of the yoke as an assembly. This assembly can be further disassembled, if desired, by removing the cap screw (key 3).
7. Take out the actuator spring (key 6) and the lower spring seat (key 11).
8. The lower diaphragm casing (key 5) can be removed from the yoke, if required, by removing the cap screws (key 8) that hold the lower diaphragm casing in place.
9. Unscrew the adjusting screw (key 12) from the yoke to complete the disassembly. Be careful not to lose the straight pin (key 89) since it could drop out of the yoke through the threaded adjusting screw hole.

Size 80 Actuators

Key number references are shown in figure 4.

1. Bypass the control valve. Reduce the actuator loading pressure to atmospheric pressure, and remove the piping or tubing from the upper diaphragm casing connection.
2. Loosen the hex nut (key 50), and back the adjustable travel stop (key 34) away from the diaphragm casings (keys 1 and 5).
3. Unbolt the cap screws (key 8), and remove the spring case assembly (key 35).
4. Measure and record how much of the actuator stem (key 10) extends past the spring adjusting screw (key 12). Using a hammer and a punch, loosen the spring adjusting screw locknut (key 91). Slip a 12.7 mm (1/2-inch)

diameter rod into a hole in the spring adjusting screw (key 12). Using the rod, turn the spring adjusting screw away from the diaphragm (key 2) to relieve all compression in the spring (key 6).

5. Loosen the hex nuts (key 16), and remove the stem connector cap screws and stem connector halves (key 26). If necessary, the actuator may be removed from the valve body by removing the valve bonnet stud bolt hex nuts.
6. Remove the spring adjusting screw (key 12), the spring seat guide (key 36), the lower spring seat (key 11), and the spring seat bearing and race (keys 41 and 42).
7. Remove the actuator spring (key 6) and the spring adjusting screw locknut (key 91).
8. Unbolt the diaphragm casing cap screws and hex nuts (keys 22 and 23), and lift the upper diaphragm casing (key 1) and attached casing flange (key 51) with seal bushing (key 46) straight up until clear of the actuator stem (key 10).
9. Remove the snap ring (key 47) and slide the seal bushing (key 46) out of the casing flange (key 51). Inspect the seal bushing for wear, and replace if necessary. Remove the seal bushing O-rings (keys 44 and 45). Separate the casing flange (key 51) from the upper diaphragm casing (key 1) by removing the cap screws (key 8). Remove the gasket (key 52) from the upper diaphragm casing (key 1).
10. Slide or lift the actuator stem (key 10) with the attached diaphragm plates and diaphragm (key 48, 4, and 1) out of the actuator.
11. To aid in unscrewing the hex nuts (key 49), attach the stem connector assembly (key 26) onto the actuator stem and grip the stem connector in a vise. This procedure will help secure the actuator stem and help prevent damage.
12. Unscrew the hex nuts (key 49), and slide them, the diaphragm plate (key 4), diaphragm (key 2), and upper diaphragm plate (key 48) off the actuator stem.
13. Remove the cap screws (key 8) that secure the lower diaphragm casing (key 5) to the actuator yoke (key 9), and remove the lower casing.

Assembly

Size 40, 45, and 70 Actuators

Key number references are shown in figure 2 for size 40 and 45 actuators and in figure 3 for size 70 actuators.

1. Apply lithium grease to the threads and spring seat bearing surface of the adjusting screw. Thread the adjusting screw (key 12) into the yoke (key 9).
2. Use the cap screws (key 8) to attach the lower diaphragm casing (key 5) to the yoke. Tighten the cap screws to 41 N•m (30 lbf•ft) for sizes 40 and 45 and 102 N•m (75 lbf•ft) for the size 70.
3. Insert the lower spring seat (key 11) and spring (key 6) into the yoke. Be sure the spring seat fits squarely on the adjusting screw and that the spring is properly seated in the spring seat.
4. Assemble the actuator stem (key 10) and the diaphragm plate (key 4) with the cap screw and washer (key 3 and 25). Tighten the cap screw in accordance with table 4. The size 40 actuator does not use a washer.
5. Insert the stem and diaphragm plate as an assembly, making sure that the stem fits inside the adjusting screw and that the spring fits squarely on the diaphragm plate.
6. Install a new diaphragm (key 2) if one is required. Otherwise, replace the molded diaphragm (key 2) onto the diaphragm plate so that the molded edge points outward toward the spring (see figures 2 and 3) and the word Fisher printed on the diaphragm is visible. Line up the holes in the diaphragm's edge with the diaphragm casing cap screw holes.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing cap screws are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 40, 45, and 70 actuators.

NOTICE

Overtightening the diaphragm casing cap screws and nuts (keys 22 and 23) can damage the diaphragm. Do not exceed a torque of 27 N•m (20 lbf•ft) when performing this tightening procedure.

Note

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

7. Place the upper diaphragm casing (key 1) into position, and replace the diaphragm casing cap screws and nuts (keys 22 and 23). Tighten the hex nuts (key 23) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to 13 N•m (10 lbf•ft).
8. Tighten the remaining hex nuts in a clockwise, crisscross pattern to 13 N•m (10 lbf•ft).
9. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
10. Tighten the remaining hex nuts in a clockwise, crisscross pattern to 27 N•m (20 lbf•ft).
11. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
12. Once completed, no more tightening is recommended.
13. Thread the spring adjusting screw (key 12) into the yoke so that it is in the same position recorded during disassembly. Securely tighten the locking set screw (key 67).
14. Replace the tubing or piping to the top of the upper diaphragm casing. Mount the actuator, and make the stem connection by following the procedures in the Actuator Mounting section.

Size 80 Actuators

Key number references are shown in figure 4.

1. Place the lower diaphragm casing (key 5) on the actuator yoke (key 9), and secure them together with the cap screws (key 8). Torque the screws evenly to 102 N•m (75 lbf•ft) using a crisscross pattern.
2. Carefully slide the upper diaphragm plate (key 48), the diaphragm (key 2), and the diaphragm plate (key 4) onto the actuator stem (key 10). Thread the two hex nuts (key 49) lightly against the diaphragm plate. To aid in tightening the hex nuts (key 49), attach the stem connector assembly (key 26) onto the actuator stem, and grip the stem connector in a vise. Tighten the first hex nut (key 49) to approximately 542 N•m (400 lbf•ft) torque. Tighten the second hex nut securely against the first. Remove the actuator stem subassembly from the vise, and remove the stem connector assembly (key 26) from this subassembly.
3. Place the actuator stem and attached parts into the lower diaphragm casing (key 5). Prop the stem up so that the diaphragm plates are positioned as shown in figure 4.
4. Lubricate the O-rings (keys 44 and 45) and the inside diameter of the seal bushing (key 46) with either a high-temperature, radiation-resistant, polyphenyl ether grease or lithium grease, as appropriate for the installation. Place the seal bushing and O-rings in the casing flange (key 51), and secure the bushing with the snap ring (key 47). Place a new gasket (key 52) and then the casing flange (key 51) onto the upper diaphragm casing (key 1). Insert and tighten the cap screws (key 8) to 102 N•m (75 lbf•ft) torque to secure the parts.
5. Align the diaphragm cap screw holes with the lower diaphragm casing cap screw holes. Slide the upper diaphragm casing and casing flange (keys 1 and 51) over the actuator stem (key 10) and onto the lower diaphragm casing (key 5) so that all cap screw holes are aligned.

Table 6. Size 80 Casing Cap Screw Torque Values

DIAPHRAGM MATERIAL	INITIAL TORQUE	FINAL TORQUE
	N•m (lbf•ft)	N•m (lbf•ft)
EPDM / Meta-Aramid	41 (30)	82 ± 13 (60 ± 10)
Nitrile, Silicone, FKM/Meta-Aramid	34 (25)	68 (50)

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing cap screws are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 80 actuators.

NOTICE

Overtightening the diaphragm casing cap screws and nuts can damage the diaphragm. Do not exceed the following maximum torque values for the appropriate diaphragm material: EPDM/Meta-Aramid: 95 N•m (70 lbf•ft); Nitrile, Silicone, FKM (fluorocarbon) / Meta-Aramid: 68 N•m (50 lbf•ft).

Note

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

- Fasten the two diaphragm casings together with the cap screws (key 22) and tighten the hex nuts (key 23) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to the initial torque value found in table 6 for the diaphragm material being used.
- Tighten the remaining hex nuts in a clockwise, crisscross pattern to the initial torque value found in table 6 for the diaphragm material being used.
- Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to the final torque value that is specified in table 6 for the diaphragm material being used.
- Tighten the remaining hex nuts in a clockwise, crisscross pattern to the final torque value that is specified in table 6 for the diaphragm material being used.
- After the last hex nut is tightened, complete another tightening sequence. Tighten in a circular pattern around the bolt circle to the final torque value that is specified in table 6 for the diaphragm material being used.
- Once completed, no more tightening is recommended.
- Thread the spring adjusting screw locknut (key 91) onto the actuator stem (key 10). Place the spring (key 6) on the casing flange (key 51).
- Assemble the spring seat and spring seat guide (keys 11 and 36). Place them on the actuator spring (key 6).
- Lubricate the spring seat race and bearings (keys 39 and 40) with lithium grease (key 53). Place them on the spring seat.
- Attach the stem connector (key 26) to the actuator stem so that the connector engages the antirotation guide on the actuator yoke. Thread the adjusting screw (key 12) onto the actuator stem until the actuator stem (key 10) extends above the adjusting screw the distance recorded in step 4 of the disassembly procedures for size 80 actuators. Securely tighten the spring adjusting screw locknut (key 91) against the spring adjusting screw (key 12).
- Connect piping or tubing to the pressure connection in the upper diaphragm casing (key 1). Pressure the actuator, and if necessary, readjust the spring compression with the adjusting screw (key 12) until the actuator fully strokes over the bench set pressure range stamped on the actuator nameplate. Remove the stem connector.

17. Lubricate the spring seat guide (key 36) and the appropriate area inside the spring case assembly (key 35) with either a high-temperature, radiation-resistant, polyphenyl ether grease or lithium grease (key 54), as appropriate for the installation.
18. Place the spring case assembly (key 35) on the upper diaphragm casing. Insert and tighten the cap screws (key 8) to 102 N•m (75 lbf•ft).
19. Thread the adjustable travel stop (key 34) into the spring case (key 35) so that the travel stop is approximately 3.2 mm (1/8-inch) from the actuator stem (key 10) when the stem is in the extreme upward position. Thread the hex locknut (key 50) against the spring case, and lock it securely against the spring case.
20. Mount the actuator, and make the stem connection by following the procedure in the Actuator Mounting section.

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always refer to this serial number when corresponding with your [Emerson sales office](#) regarding replacement parts or technical information.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts List

Key	Description	Key	Description
1	Upper Diaphragm Casing, steel Std Size 40, 45, 70, and 80 W/top-mounted handwheel Size 40, 45, and 70	23	Hex Nut, pl steel Size 40 (16 req'd) Size 45 (20 req'd) Size 70 (28 req'd) Size 80 (36 req'd)

Introduction

Scope of Manual

This instruction manual provides information on installation, adjustment, maintenance, and parts ordering for the Fisher 667 actuator in sizes 30/30i through 76/76i and size 87. The 667-4 actuator in sizes 70/70i and 87 is also covered. Refer to separate instruction manuals for information about the valve positioner and other accessories used with these actuators.

Do not install, operate, or maintain a 667 actuator (see figure 1) without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

667 Actuator (Size 30/30i - 76/76i and 87)

May 2018

	Silicone Elastomers	-54 to 149°C (-65 to 300°F)									

1. These values also apply to the 667-4 actuator construction.
 2. Actuator travel may be less than the value listed after connected to the valve.
 3. Maximum actuator travel for 667-4 is 102 mm (4 inches).
 4. See also the Specifications portion of the introduction section.
 5. Additional pressure may be added when the actuator is at full travel. If the Maximum Excess Diaphragm Pressure is exceeded, damage to the diaphragm or diaphragm casing might result. See the Maximum Pressure Limitation section.
 6. Maximum diaphragm casing pressure must not be exceeded and must not produce a force on the actuator stem greater than the maximum allowable actuator output thrust or the maximum allowable stem load. See the Maximum Pressure Limitation section.
 7. This maximum casing pressure is not to be used for normal operating pressure. Its purpose is to allow for typical regulator supply settings and/or relief valve tolerances.

Description

The 667 actuator (figure 1) and the 667-4 actuator are reverse-acting, spring-opposed diaphragm actuators. They provide automatic operation of control valves. The 667 actuator provides 76 mm (3 inches) maximum actuator travel. The 667-4 actuator provides 102 mm (4 inches) maximum actuator travel. Both actuators position the valve plug in response to varying pneumatic loading pressure on the diaphragm. Figure 2 shows the operation of these actuators.

A 667 or 667-4 actuator can be furnished with either a top-mounted or a side-mounted handwheel assembly. A top-mounted handwheel assembly is normally used as an adjustable down travel stop. (A down travel stop limits actuator travel in the down direction [when the stem is traveling out of the actuator]. Travel in the up direction is when the stem is traveling into the actuator.) A side-mounted handwheel assembly is normally used as an auxiliary manual actuator. The side-mounted handwheel can also be used as an adjustable up or down travel stop. Casing-Mounted adjustable up or down travel stops are also available on this actuator.

Note

If repeated or daily manual operation is expected, the actuator should be equipped with a side-mounted handwheel rather than a casing-mounted travel stop or top-mounted handwheel. The side-mounted handwheel is designed for more frequent use as a manual operator.

Figure 2. Schematic of Fisher 667 and 667-4 Actuators

Specifications

Refer to table 1 for Specifications of the 667 and 667-4 actuators. See the actuator nameplate for specific information for your actuator.

[Click here](#) or access the following QR code for a video on installing a side-mounted handwheel on a 667 actuator.

⚠ WARNING

To avoid personal injury or damage to equipment that may result in the malfunction of the control valve or loss of control of the process caused by excessive pressure, do not exceed the Maximum Pressures listed in table 1. Refer to the Maximum Pressure Limitations section.

Maximum Pressure Limitations

The casing and diaphragm of 667 actuators are pressure operated. This air pressure provides energy to compress the spring, to stroke the actuator, and to seat the valve. The following explanations describe the maximum pressure limits for an actuator. Refer to the nameplate or table 1 for maximum values for your actuator.

- **Maximum Casing Pressure for Actuator Sizing:** This is the maximum pressure that can be applied at less than full travel of the actuator. If this stroking pressure is exceeded before the upper diaphragm plate contacts the travel stop, damage to the stem or other parts might result.
- **Maximum Excess Diaphragm Pressure:** Additional pressure may be added when the actuator is at full travel. If the Maximum Excess Diaphragm Pressure is exceeded, damage to the diaphragm or diaphragm casing might result.

Because the actuator has traveled its specified travel, and the diaphragm head is physically stopped from movement, the energy from any additional air pressure is transmitted to the diaphragm and diaphragm casings. The amount of air pressure that can be added once the actuator has traveled to the stops is limited by the resultant adverse effects that may occur. Exceeding this limiting factor could result in leakage or casing fatigue due to the deformation of the upper diaphragm casing.

- **Maximum Diaphragm Casing Pressure:** If the Maximum Diaphragm Casing Pressure is exceeded, damage to the diaphragm, diaphragm casing, or actuator might result.

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations.

Check with your process or safety engineer for any other hazards that may be present from exposure to process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

Key number locations are shown in figures 6, 7, 8, 9, and 10, unless otherwise noted. Also, refer to figure 3 for location of parts.

CAUTION

To avoid parts damage, do not use an operating pressure that exceeds the Maximum Diaphragm Casing Pressure (table 1) or produces a force on the actuator stem greater than the Maximum Allowable Output Thrust (table 1) or the Maximum Allowable Valve Stem Load.

- **Valve/Actuator Assembly:** If the actuator and valve are shipped together as a control valve assembly, it has been adjusted at the factory, and may be installed in the pipeline. After installing the valve in the pipeline, refer to the Loading Connection procedures.
- **Actuator Mounting:** If the actuator is shipped separately or the actuator has been removed from the valve, it is necessary to mount the actuator on the valve before placing the valve in the pipeline. Refer to the following actuator mounting procedures before placing the valve in service. It is recommended that you perform the Bench Set Spring Adjustment procedures in this section to confirm that the actuator is adjusted correctly for the valve travel.
- **Positioner:** If a positioner is installed, or is to be installed on the actuator, refer to the positioner instruction manual for installation. During the adjustment procedures, it will be necessary to provide a temporary loading pressure to the actuator diaphragm.
- **Handwheel Cap:** If the handwheel cap (key 247, figures 11, 13, or 21) is not in place, install the cap by pushing it on by hand until it snaps into place.

Mounting the Actuator on the Valve

CAUTION

The 667 actuator spring load pushes the stem down out of the actuator yoke (see figure 2), and it can come in contact with the valve stem during actuator mounting.

If the valve stem is allowed to remain in the up position (towards the actuator) during actuator mounting, it can interfere with the actuator stem during mounting. It is possible to damage valve stem threads or bend the valve stem. Be sure the valve stem is pushed down (into the valve body), away from the actuator while mounting.

It may be necessary to apply a temporary loading pressure to the actuator to move the actuator stem away from the valve during installation.

If it is not possible to provide a temporary loading pressure, be very careful when lowering the actuator over the valve stem to prevent damage to valve stem and threads.

⚠ WARNING

When moving the actuator stem with loading pressure applied, exercise caution to keep hands and tools out of the actuator stem travel path. If the loading pressure is accidentally disconnected, personal injury and property damage may result if something is caught between the actuator stem and other control valve parts.

1. Provide a vise or some other method of supporting the valve and the weight of the actuator during assembly. For direct or reverse acting valves, push the valve stem down away from the actuator while mounting the actuator.
2. Screw the stem locknuts all the way onto the valve stem. With the concave side of the travel indicator disk (key 34) facing the valve, install the travel indicator disk on the valve stem. (Note: The travel indicator disk is not used with size 87 actuators.)
3. Lift or hoist the actuator onto the valve bonnet:
 - a. For size 87 actuators: Slowly lower the actuator down onto the valve while guiding the valve stem into the opening in the end of the actuator stem (see figure 4). Once the actuator is in place, insert the cap screws and tighten the hex nuts, securing the actuator to the bonnet.

b. For all other size actuators:

- Slowly lower the actuator down onto the valve. As the yoke passes over the end of the valve stem, place the yoke locknut over the valve stem. (Note: On small size actuators, it may be necessary to remove the indicator disk and re-install it while lowering the actuator onto the valve because the disk will not go through the actuator yoke opening).
 - Continue to lower the actuator while guiding the valve stem into the opening in the end of the actuator stem until the actuator is in place (see figure 4).
 - Screw the yoke locknut onto the valve bonnet and tighten the locknut.
4. Do not connect the actuator stem to the valve stem at this time. Whenever the actuator is installed on the valve, it is recommended that you perform the Bench Set Spring Adjustment procedures below, to verify that the actuator is still adjusted correctly.

Figure 3. Actuator-Mounting Components for Size 30/30i through 70/70i Actuators

Discussion of Bench Set

The bench set pressure values are used to adjust the initial compression of the actuator spring with the valve-actuator assembly “on the bench.” The correct initial compression ensures that the valve-actuator assembly will function properly when it is put into service and the proper actuator diaphragm operating pressure is applied.

The bench set values are established with the assumption that there is no packing friction. When attempting to adjust the spring in the field, it is very difficult to ensure that there is no friction being applied by “loose” packing.

Accurate adjustment to the bench set range can be made during the actuator mounting process by making the adjustment before the actuator is connected to the valve (see the Spring Verification Procedure).

Figure 4. Bench Set Adjustment

Spring Verification

Ensure that the actuator diaphragm is at the bottom of its travel as shown in figure 4 and not connected to the valve. (Note: Some spring compression is required to move the diaphragm to the **bottom** of its travel.)

Also, provide a certified pressure gauge that will accurately read the diaphragm pressure from 0 through 0.3 bar (5 psig) above the upper operating range pressure marked on the nameplate. Apply loading pressure to the diaphragm.

Stroke the actuator a few times to ensure that the pressure gauge is working correctly, and that the actuator is functioning properly.

CAUTION

To prevent actuator damage, it is important to ensure that the actuator stem is stroking smoothly and not exhibiting binding or excessive friction between the actuator stem and the bushing (key 7). Binding or excessive friction could be an indicator of incorrect assembly or damaged parts.

Key numbers are shown in figures 6, 7, 8, 9, and 10.

Note

For 667 actuators installed on push-down-to-close (direct acting) valves with fail-close action, the valve plug seat is the limit for downward travel and the actuator is the limit for upward (away from the valve) movement.

For 667 actuators installed on push-down-to-open (reverse acting) valves with fail-open action, the actuator down stop is the limit for downward movement, and the valve seat is the limit for upward (away from the valve) movement.

Ensure the correct Spring Verification procedure is followed for the type of valve on which the 667 actuator is installed.

For Push Down to Close (Direct Acting) Valves

1. If not already accomplished, push the valve stem down away from the actuator to the closed position.
2. Set the diaphragm loading pressure to 0.3 bar (5 psig) over the upper operating range pressure. The travel stop cap screw (key 12) should be contacting the upper diaphragm casing.
3. Slowly decrease the pressure towards the upper bench set pressure, as indicated on the nameplate, while checking for the **first** linear movement of the actuator stem.

Note

Before turning the spring adjuster on size 70/70i, 76/76i, or 87 actuators, assemble the stem connector around the actuator stem and the anti-rotating lug on the yoke. Mark the actuator stem as a visual reference to verify that stem rotation does not occur. Remove the stem connector before rechecking the bench set.

4. If movement occurs before or after the upper bench set pressure is reached, adjust the spring adjuster (see figure 4). Thread the adjuster up or down on the actuator stem until the actuator stem movement is **first** detected at the upper bench set pressure. (Note: You may need to lower the loading pressure to reduce spring compression, allowing the spring adjuster to turn.)
5. Be sure the spring adjuster is adjusted to meet the requirements of step 4 above.
6. Slowly decrease diaphragm loading pressure to the lower bench set pressure, as indicated on the nameplate. This will extend the actuator stem toward the valve. Mark the end of the actuator stem on a nearby surface using tape or some other method.
7. Slowly increase the diaphragm loading pressure until the upper bench set pressure is reached. Again, the travel stop cap screw (key 12) should be against the upper diaphragm casing.
8. Measure the distance between the mark or tape to the end of the actuator stem. This distance should match the rated travel indicated on the nameplate.
9. If the measured travel matches the nameplate travel, bench set is complete. Proceed to the Installing the Stem Connector Assembly subsection.
10. If the measured travel is not exact, consider the spring free-length and spring rate tolerances may produce a slightly different bench set than specified. Contact your Emerson Automation Solutions sales office for assistance.

For Push Down to Open (Reverse Acting) Valves

1. If not already accomplished, push the valve stem down away from the actuator to the open position. Later, when installing the connector, pull up the valve stem to the closed position.

2. Set the diaphragm loading pressure to a value less than the lower bench set pressure, as indicated on the nameplate, or near zero. The down travel stops (key 77) should be contacting the yoke.
3. Slowly increase the pressure towards the lower bench set pressure while checking for the **first** linear movement of the actuator stem.

Note

Before turning the spring adjuster on size 70/70i, 76/76i, or 87 actuators, assemble the stem connector around the actuator stem and the anti-rotating lug on the yoke. Mark the actuator stem as a visual reference to verify that stem rotation does not occur. Remove the stem connector before rechecking the bench set.

4. If movement occurs before or after the lower pressure is reached, adjust the spring adjuster (see figure 4). Thread the adjuster up or down on the actuator stem until the actuator stem movement is **first** detected at the lower bench set pressure.
5. Apply the upper bench set pressure indicated on the nameplate to the diaphragm. This will retract the actuator stem away from the valve. Mark the end of the actuator stem on a nearby surface using tape or some other method.
6. Slowly decrease the diaphragm pressure until the lower bench set pressure is applied. Again, the down travel stops (key 77) should be against the yoke.
7. Measure the distance between the mark or tape to the end of the actuator stem. This distance should match the rated travel indicated on the nameplate.
8. If the measured travel matches the nameplate travel, bench set is complete. Proceed to the Installing the Stem Connector Assembly subsection.
9. If the measured travel is not exact, consider the spring free-length and spring rate tolerances may produce a slightly different bench set than specified. Contact your Emerson Automation Solutions sales office for assistance.

Installing the Stem Connector Assembly

When installing the stem connector assembly (key 31), the actuator and valve stem threads should engage the threads of the stem connector by a distance equal to the diameter of the stem.

WARNING

Install the stem connector securely before a positioner is mounted to the actuator and pressurized, using only a regulator-controlled air supply, not the positioner, to move the actuator stem.

To avoid personal injury or property damage, keep hands and tools out of the actuator stem travel path while applying loading pressure to move the actuator stem in the following steps.

CAUTION

To avoid damaging the seating surfaces, do not rotate the valve plug while it is seated. Exercise care while installing the stem connector assembly to avoid damage to the valve plug stem and valve stem threads.

Note

Replacement stem connectors are an assembly of two stem connector halves, cap screws, and a spacer between the connector halves. Remove the spacer and discard it, if present, before clamping the actuator and valve stems together. Use only a mated pair of stem connectors.

1. If necessary, push the valve stem down so that the valve plug is touching the seat ring on direct-acting valves. For reverse-acting valves, pull the stem up to the closed position. Always start with the valve plug on the seat.
2. If necessary, screw the valve stem locknuts down, away from the connector location. For all actuators except size 87, ensure that the travel indicator disk (key 34) is on top of the locknuts.
3. Adjust the diaphragm pressure to the lower bench set pressure (or, the upper bench set pressure for reverse-acting valves.) This should be the same pressure used in the Spring Verification steps, and it is marked on the nameplate.
4. Place the stem connector half with the threaded holes approximately half way between the actuator and valve stems, and align the actuator stem and valve stem with threads from both stems mated root-to-crest with the stem connector. If the threads from one of the stems do not fully align with the stem connector, a slight change to loading pressure may be necessary to align the threads. Refer to figures 6, 7, 8, 9, and 10 to help locate the connector position.

CAUTION

Incomplete engagement of either the valve stem or actuator stem in the stem connector can result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than one diameter of that stem. Damage to threads on either stem or in the stem connector can cause the parts to be replaced prematurely. Do not loosen the cap screws when the stem connector has spring or loading pressure force applied.

5. Install the other half of the stem connector and insert the cap screws and tighten them while ensuring even spacing between the stem connector halves on all sides. If installing a positioner, also attach the feedback bracket at the same time.

CAUTION

Over-tightening the valve stem locknuts can make disassembly difficult.

6. Screw the valve stem locknuts up against the stem connector for the size 87 actuator. For all other actuator sizes, screw the valve stem locknuts up until the indicator disk contacts the bottom of the stem connector. Do not overtighten the locknuts.
7. Slowly stroke the valve from fully open to fully closed and verify full rated travel is achieved.

Be sure that the valve is in the closed position. Loosen the screws on the travel indicator scale (key 32), and align it with the travel indicator disk (key 34). Stroke the valve full travel to ensure that the travel matches the rated valve travel on the nameplate. If valve travel is not correct, repeat the stem connector procedure.

Friction Discussion

If you are attempting to adjust the bench set after the actuator is connected to the valve and the packing tightened, you must take friction into account. Make the spring adjustment so full actuator travel occurs at the bench set values (a) plus the friction force divided by the effective diaphragm area with increasing diaphragm pressure or (b) minus the friction force divided by the effective diaphragm area with decreasing diaphragm pressure.

If the stem connector assembly has been installed, the valve friction may be determined by the following procedure:

1. Install a pressure gauge in the actuator loading pressure line that connects to the actuator diaphragm casing.

Note

Steps 2 and 4 require that you read and record the pressure shown on the pressure gauge.

2. Increase the actuator diaphragm pressure and read the diaphragm pressure as the actuator reaches a travel position in the rated travel of the valve that does not contact a travel stop. Make a reference mark on the travel indicator scale using tape or some other method at this point.
3. Increase the actuator diaphragm pressure until the actuator is at a travel position greater than the position referenced in step 2 using the reference point to identify first movement.
4. Decrease the actuator diaphragm pressure and read the diaphragm pressure as the actuator returns to the position referenced in step 2.

The difference between the two diaphragm pressure readings is the change in the diaphragm pressure required to overcome the friction forces in the two directions of travel.

5. Calculate the actual friction force:

$$\text{Friction Force, = pounds} = 0.5 \left(\begin{array}{c} \text{Difference} \\ \text{in pressure} \\ \text{readings, psig} \end{array} \right) \times \left(\begin{array}{c} \text{Effective} \\ \text{diaphragm area,} \\ \text{inches}^2 \end{array} \right)$$

Refer to table 1 for the effective diaphragm area.

It is difficult to rotate the spring adjustor (key 74, figures 6, 7, 8, 9, and 10) when the full actuator loading pressure is applied to the actuator. Release the actuator loading pressure before adjusting. Then re-apply loading pressure to check the adjustment.

Figure 5. Typical Valve Response to Deadband

NOTE:

1

DEADBAND IS CAUSED BY FRICTION.

A6763-2

Deadband Measurement

Deadband is caused by packing friction, unbalanced forces, and other factors in the control valve assembly. Deadband is the range a measured signal can vary without initiating a response from the actuator (see figure 5). Each actuator spring has a fixed spring rate (force divided by compression). You have verified that the right spring was installed in the actuator by completing the Spring Verification steps.

Deadband is one factor that affects the control valve assembly operation during automatic loop control. The control loop tolerance for deadband varies widely depending on the loop response. Some common symptoms of the

deadband being too wide are no movement, a “jump” movement, or oscillating movements of the actuator during automatic loop control. The following steps are provided to determine the span of deadband. The percent of deadband is helpful in troubleshooting problems with the process control loop.

1. Start at a pressure near the lower bench set pressure, slowly increase pressure until the valve is approximately at mid-travel. Note this pressure reading.
2. Slowly decrease pressure until movement of the valve stem is detected, and note this pressure.
3. The difference between these two pressures is deadband, in psi.
4. Calculate the percent of deadband by:

Deadband, psi

$$\text{Deadband} = \frac{\text{Deadband, psi}}{\text{Bench Set Span, psi}} = \text{nn \%}$$

Loading Connection

Key number locations are shown in figures 6, 7, 8, 9, and 10, unless otherwise noted.

The loading pressure connections are made at the factory if the valve, actuator, and positioner come as a unit. Keep the length of tubing or piping as short as possible to avoid transmission lag in the control signal. If a volume booster, valve positioner, or other accessory is used, be sure that it is properly connected to the actuator. Refer to the positioner instruction manual or other manuals as necessary. For actuators shipped separately or whenever the actuator pressure connections are installed, use the following steps:

1. Connect the loading pressure piping to the NPT internal connection in the side of the yoke (key 73).
2. For size 70/70i and 87 actuators, if necessary, remove the 1/4 NPT bushing if a 1/2 NPT internal connection is needed to increase connection size. The connection can be made with either piping or tubing.
3. Cycle the actuator several times to be sure that the valve stem travel is correct when the correct pressure ranges are applied to the diaphragm.
4. If valve stem travel appears to be incorrect, refer to the Bench Set Spring Adjustment procedures at the beginning of this section. Do not place the valve in service if it is not reacting correctly to diaphragm loading pressure changes.

Maintenance

Actuator parts are subject to normal wear and must be inspected regularly and replaced when necessary. The frequency of inspection and replacement depends on the severity of service conditions.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.

- Vent the power actuator loading pressure and relieve any actuator spring pre-compression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

The maintenance instructions are divided into several sections: Actuator, Top-Mounted Handwheel Assembly (Adjustable Down Travel Stop), Side-Mounted Handwheel Assembly for Size 34/34i through 60/60i Actuators (Manual Actuator), Side-Mounted Handwheel Assembly for Size 70, 76 and 87 Actuators (Manual Actuator), and Casing-Mounted Travel Stops.

Actuator

This procedure describes how the actuator can be completely disassembled and assembled. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job; then, start the assembly at the appropriate step.

Key numbers are shown in figures 6, 7, 8, 9, or 10, unless otherwise noted. Figure 6 shows the size 30 through 60 actuators, figure 7 shows the size 30i through 60i actuators, figure 8 shows the size 70 actuator, figure 9 shows the size 70i actuator, and figure 10 shows the size 87 actuator.

Actuator Disassembly

Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

1. If equipped, remove the tubing or piping from the connection in the top of the yoke (key 73).
2. Turn the spring adjuster (key 74) counterclockwise (**toward the valve body**) until all spring compression is relieved.

WARNING

To avoid personal injury due to the sudden uncontrolled movement of parts, do not loosen the stem connector cap screws when the stem connector has spring force applied to it.

3. If necessary, remove the actuator from the valve body by separating the stem connector (key 31). Loosen the stem locknuts for the size 87 actuator, and remove the stem connector nuts. For all other sizes, separate the stem connector by loosening the stem locknuts (keys 69 and 75) and unscrewing the two stem connector cap screws.
4. Unscrew the spring adjuster (key 74) from the actuator stem (key 144). Also lift the spring seat and spring (key 19 and 18) out of the yoke.
5. Remove the diaphragm casing cap screws and nuts (keys 13 and 14), and lift off the upper diaphragm casing (key 1).

CAUTION

Be careful during disassembly to avoid damaging the O-rings (key 8).

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

667 Actuator (Size 30/30i - 76/76i and 87)

May 2018

Instruction Manual

D100310X012

6. Remove the following connected parts: the diaphragm (key 3), upper diaphragm plate (key 4), spacer (key 2), cap screw (key 12), lower diaphragm plate (key 71), and actuator stem (key 144). Be careful when pulling the threads of the actuator stem through the seal bushing (key 7) to avoid damaging the O-rings (key 8).
7. Remove the cap screw (key 12) to separate the parts of this assembly.
8. To remove the seal bushing, remove the snap ring (key 72), and lift out the bushing. Inspect, and if necessary, replace O-rings (keys 8 and 9).
9. Remove cap screws (key 30), and take off the lower diaphragm casing (key 64) and the gasket (key 70, size 30/30i through 60/60i and 76/76i) or O-ring (key 70, size 70/70i or 87). If necessary, the down travel stops (key 77) can be removed.

Table 2. Actuator Assembly Recommended Torque Values

DESCRIPTION, KEY NUMBER	ACTUATOR SIZE	THREAD SIZE, INCH	TORQUE	
			N • m	Lbf • ft
Casing to yoke, key 30 ⁽¹⁾	30/30i to 60/60i and 76/76i	3/8-16	41	30
	70/70i and 87	1/2-13	95	70
Travel stop, key 12	30/30i	3/8-24	41	30
	34/34i and 40/40i	1/2-20	68	50
	45/45i to 76/76i and 87	3/4-16	183	135
MO U-bolt nut, key 170	34 and 40	1/2-13	81	60
	45 to 60	5/8-11	163	120
MO U-bolt nut, key 147	34 and 40	3/8-16	41	30
MO U-bolt nut, key 144	45 to 60	3/8-16	41	30
Diaphragm casing, key 14 ⁽¹⁾	30/30i to 76/76i and 87	3/8-24	27	20
Hex cap screw, key 256	34i to 40i	1/2-13	92	68
	45i to 60i	5/8-11	163	120
Hex cap screw, key 257	34i to 60i	3/8-16	39	29
Stem connector, key 26 ⁽²⁾	30/30i through 40/40i	5/16-18	23	17
	45/45i through 70/70i	3/8-16	39	29
	87	1/2-13	91	67

1. Observe tightening pattern and procedure described in the appropriate Actuator Assembly section.
2. Torque values when lithium grease is used on the threads.

Actuator Assembly

Refer to table 2 as appropriate.

1. Coat the O-rings (key 70/70i, sizes 70 and 87) with lithium grease (key 237), or, coat the gasket with lithium grease (key 237). Place a new gasket or O-ring (key 70) on the yoke (key 73). Position the lower diaphragm casing (key 64) on the yoke and align the holes. Insert the cap screws (key 30) and tighten evenly in a crisscross pattern to 41 N•m (30 lbf•ft) for size 30/30i-60/60i and 76/76i actuators or 95 N•m (70 lbf•ft) for size 70/70i and 87 actuators. If down travel stops (key 77) were removed, insert and tighten them.
2. Coat the O-rings (keys 8 and 9) with lithium grease (key 237) and place the O-rings in the seal bushing (key 7).
3. Fill the seal bushing with lithium grease (key 237), slide the bushing into the yoke (key 73), and install the snap ring (key 72).

CAUTION

Be careful during assembly to avoid damaging the O-rings (key 8).

4. Assemble the actuator stem (key 144), lower diaphragm plate (key 71), diaphragm (key 3), upper diaphragm plate (key 4), and the travel stop cap screw and spacer (keys 12 and 2). Coat the cap screw threads with lithium grease

(key 237). Tighten the cap screw (key 12) to the appropriate torque as shown in table 2. Place this assembly in the actuator. Take care when pushing the actuator stem through the seal bushing so that the threads do not damage the O-rings.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 30/30i-76/76i and 87 actuators.

CAUTION

Over-tightening the diaphragm cap screws and nuts (keys 13 and 14) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

5. Install the upper diaphragm casing (key 1), and install the cap screws and nuts (keys 13 and 14). Tighten the diaphragm cap screws and nuts in the following manner.
6. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 13 N•m (10 lbf•ft).
7. Tighten the remaining bolts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
8. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
9. Tighten the remaining bolts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
10. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
11. Once completed, no more tightening is recommended.
12. Install the actuator spring (key 18) and spring seat (key 19). Apply anti-seize lubricant (key 239) to the threads of the actuator stem and to the surface of the spring adjuster (key 74) that contacts the spring seat. Thread the spring adjuster onto the actuator stem.
13. Mount the actuator onto the valve in accordance with the procedures in the Installation section.

Top-Mounted Handwheel Assembly (Adjustable Down Travel Stop)

Actuator key numbers are shown in figures 6, 7, 8, 9, and 10. And, top-mounted handwheels are shown in figures 11, 12, 13, 14, and 15.

Note

If repeated or daily manual operation is expected, the actuator should be equipped with a side-mounted handwheel rather than a casing-mounted travel stop or top-mounted handwheel. The side-mounted handwheel is designed for more frequent use as a manual operator.

A top-mounted handwheel assembly (figures 11, 12, 13, 14, and 15) is usually used as an adjustable down travel stop to limit full extension of the actuator stem. Turning the handwheel counterclockwise pulls the extension rod (key 150, figures 11, 13, and 14) up, retracting the actuator stem.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Note

For size 70/70i and 87 actuators with handjack bars (figure 15) it is recommended that the handjack bar (key 58) be removed when not in use and the handwheel cap (key 247) be installed for weather protection of the internal components.

Disassembly for Top-Mounted Handwheel

1. Bypass the control valve, reduce loading pressure to atmospheric, and if equipped, remove the tubing or piping from the connection in the top of the yoke (key 73, figures 6, 8, 9, and 10).
2. Turn the handwheel (key 58) clockwise so that the handwheel assembly is not causing any spring compression.
3. Turn the actuator spring adjuster (key 74) to relieve all the compression from the spring (key 18).
4. If servicing just the thrust bearing, races, and handwheel screw (keys 180, 181, and 160), use the following steps:
 - Remove the cap and take out the cotter pin. Remove the castle nut, bearing retainer, thrust bearing, and races (keys 247, 167, 166, 180, and 181).
 - Use the handwheel to remove the handwheel screw (key 160) from the handwheel body (key 148).
 - If necessary, remove the extension rod (key 150) at this time. Most maintenance procedures do not require the rod to be removed.
 - Clean and inspect all parts or replace parts as necessary. Upon re-assembly, lubricate handwheel threads, bearings, and races with anti-seize lubricant (key 239).
 - Lubricate and re-install the handwheel screw into handwheel body (key 148). Lubricate and replace the races, bearing, and retainer (keys 181, 180, and 182). Replace the castle nut (key 166), tighten it, and insert the cotter pin (key 167). Replace the handwheel cap (key 247).
5. For size 30/30i through 60/60i and 76/76i actuator handwheels (figures 11 and 13):
 - Remove the cap screws (key 161). Make sure that the guide plate can turn between the handwheel body and the mounting plate (keys 157, 148 and 158).
 - Remove the cap (key 247) and cotter pin (key 167). Remove the castle nut (key 166) and, if necessary, unscrew the extension rod (key 150). Remove the rod, the handwheel body (key 148), and the attached parts.
 - Remove the hex nuts and cap screws (keys 14 and 13, figures 6, 7, 8, 9, and 10) from the diaphragm casings. Lift off the upper diaphragm casing (key 1) and the mounting plate (key 158).
 - Turn the handwheel (key 58) to remove the handwheel screw (key 160) from the handwheel body (key 148). Remove the retaining ring (key 60) if the handwheel (key 58) must be separated from the handwheel screw.
 - If necessary, perform other actuator maintenance before returning to the following assembly steps.

6. For size 70/70i and 87 actuator handwheels (figures 14 and 15):

- Remove the cap (key 247). Take out the cotter pin (key 167) and remove the castle nut, the bearing retainer, and thrust bearing (keys 166, 182, 181, and 180). It is not necessary to remove the extension rod (key 150) at this time.
- Remove the hex nuts and cap screws (keys 14 and 13, figures 6, 7, 8, 9, and 10) from the diaphragm casings. Lift off the upper diaphragm casing (key 1), handwheel body (key 148) and attached parts.
- If travel stops (key 152) are used, note and record their position relative to the cap screws (key 154) for use in assembly. Remove the travel stops and cap screws, and remove either the mounting plate (key 158, figure 14) or the handwheel body (key 148, figure 14) and attached parts.
- Turn the handwheel (key 58) to remove the handwheel screw (key 160) from the handwheel body (key 148). Remove the retaining ring (key 60) if the handwheel (key 58) must be separated from the handwheel screw.
- If necessary, perform other actuator maintenance before returning to the following assembly steps.

Assembly for Top-Mounted Handwheel

For size 30/30i through 60/60i and 76/76i actuator handwheels:

Refer to figures 11, 12, and 13 for top-mounted handwheel assemblies.

1. If it was removed, slide the handwheel (key 58) onto the end of the handwheel screw (key 160), and snap the retaining ring (key 60) into place. Also, install the guide post (key 150) if it was removed.
2. Generously coat the threads of the handwheel screw (key 160) with anti-seize lubricant (key 239). Turn the screw into the handwheel body (key 148).
3. Install the mounting plate (key 158) to the diaphragm casing (key 1, figures 6, 8, 9, and 10) with the cap screws (key 154). Finger tighten the screws.
4. If travel stops were used, install the travel stops to their original positions as recorded in the proceeding Disassembly steps. Tighten the screws and travel stops.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 30/30i-76/76i and 87 actuators.

CAUTION

Over-tightening the diaphragm cap screws and nuts (keys 13 and 14) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

5. Position the diaphragm casing (key 1, figures 6, 7, 8, 9, and 10), mounting plate (key 158), travel stops (key 152), if used, and cap screws (key 154) on the diaphragm. Install the cap screws and hex nuts (keys 13 and 14, figures 6, 7, 8, 9, and 10) and tighten in the following manner.

6. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 13 N•m (10 lbf•ft).
7. Tighten the remaining bolts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
8. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
9. Tighten the remaining bolts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
10. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
11. Once completed, no more tightening is recommended.
12. If necessary, screw the extension rod (key 150) into the connector (key 27). Slide the guide plate (key 157) onto the extension rod (key 150). For size 45/45i through 76/76i, place the spacer (key 253) on top of the guide plate (key 157). If necessary, replace the extension rod (key 150). Slide the handwheel body (key 148) over the extension rod, position the handwheel body on the spacer (key 253), align the holes, and insert and tighten the cap screws (key 161).
13. Lubricate and install the thrust bearings (keys 181 and 180), install the bearing retainer (key 182), install the castle nut (key 166) on the extension rod. Do not overtighten the castle nut on the bearing. Install the cotter pin (key 167). Replace the cap (key 247).
14. Refer to the Assembly portion of the Actuator maintenance section.

For size 70/70i and 87 actuators handwheels (figures 14 and 15):

Refer to figure 14 for top-mounted handwheel assemblies and figure 15 for handjack bar assemblies.

1. If removed, slide the handwheel (key 58) onto the end of the handwheel screw (key 160), and snap the retaining ring (key 60) into place.
2. Generously coat the threads of the handwheel screw (key 160) with anti-seize lubricant (key 239). Turn the screw into the handwheel body (key 148).
3. If necessary, install the extension rod (key 150) into the connector (key 27) and tighten it. Position the handwheel body (key 148) on the diaphragm casing (key 1, figures 6, 7, 8, 9, and 10), and align the holes. Insert the cap screws (key 154). Finger tighten the screws.
4. If travel stops were used, return the travel stops to their original positions as recorded in the proceeding Disassembly steps. Tighten the screws and travel stops.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 30/30i-76/76i and 87 actuators.

CAUTION

Over-tightening the diaphragm cap screws and nuts (keys 13 and 14) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

5. Slide the extension rod (key 150) into the handwheel screw (key 160), and position the diaphragm casing (key 1, figures 6, 7, 8, 9, and 10) with the attached parts on the diaphragm. Install the cap screws and hex nuts (keys 13 and 14, figures 6, 7, 8, 9, and 10) and tighten in the following manner.
6. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 13 N•m (10 lbf•ft).
7. Tighten the remaining bolts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
8. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
9. Tighten the remaining bolts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
10. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
11. Once completed, no more tightening is recommended.
12. Lubricate and install the thrust bearings (keys 180 and 181), install the bearing retainer (key 182), install the castle nut (keys 166) on the extension rod. Do not overtighten the castle nut on the bearing. Install the cotter pin (key 167). Replace the cap (key 247).
13. Refer to the Assembly portion of the Actuator maintenance section.

Side-Mounted Handwheel for Sizes 34 through 60 and 34i through 60i Actuators

A side-mounted handwheel assembly is normally used as a manual actuator for sizes 34 through 60 (figures 16 and 18) and 34i through 60i actuators (figures 17 and 19). Turning the handwheel counter-clockwise past the neutral position opens the valve. Two levers (key 146, figures 16, 17, 18, and 19) on a handwheel assembly operate the valve by moving the valve stem.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then begin the assembly at the appropriate step.

Disassembly for Side-Mounted Handwheel (Sizes 34-60 and 34i-60i)

1. Use step a. for size 34 through size 60 actuators, and use step b. for sizes 34i through 60i.
 - a. **For Size 34 through 60:** If desired, the handwheel assembly can be removed from the actuator yoke. To do this, remove the hex nuts (keys 147 and 170) from the U-bolts (key 166 and 143) that hold the assembly to the yoke for the size 30 and size 40. Remove the hex nuts (key 144 and 170) from the U-bolts (key 166 and 143) that hold the assembly to the yoke for the size 45 through size 60.
 - b. **For Size 34i through 60i:** If desired, the handwheel assembly can be removed from the actuator yoke. To do this, remove the cap screws (key 256 and 257) and spacers (key 258) that hold the assembly to the yoke for the size 30i through size 60i.
2. Remove the retaining ring (key 154) and drive out the lever pivot pin (key 153).
3. Two screws (key 156) hold the right- and left-hand levers (key 146) together. Remove the screw from the top of the levers so that the levers will drop down out of the assembly. Disassemble further, if necessary, by removing the other screw.
4. Remove the screw (key 161) and pointer mounting bolt (key 159, not shown) located behind the pointer (key 160).
5. Remove the stop nut (key 54), lockwasher (key 150), and washer (key 149). Then remove the handwheel (key 51), being careful not to lose the small ball (key 55) and spring (key 56).
6. Loosen the locking set screw (key 168, figure 19). Then, using a suitable tool, unscrew the bearing retainer (key 136).

7. Pull the handwheel screw assembly (key 145) out of the handwheel body. The operating nut (key 132) will come out with the screw. Also remove the bushing (key 151, figure 16 or 17) on size 34 and 40.
8. If required, remove the two ball bearings (key 152), one from the bearing retainer and the other from the handwheel body.

Assembly for Side-Mounted Handwheel (Sizes 34-60 and 34i-60i)

[Click here](#) or access the following QR code for a video on installing a side-mounted handwheel on a 667 actuator.

1. Pack the ball bearings (key 152) with anti-seize lubricant (key 244). Insert one bearing and the bushing (key 151, figure 16 or 17) into the handwheel body (key 142). The bushing is not used in a handwheel assembly for sizes 45/45i through 60/60i actuators.
2. Coat the handwheel screw assembly (key 145) threads with anti-seize lubricant (key 244), and thread the operating nut (key 132) onto the screw. Slide the second ball bearing (key 152) onto the screw, and insert the end of the screw into either the bushing (key 151, figure 16 or 17) for sizes 34/34i and 40/40i, or into the bearing for sizes 45/45i through 60/60i.
3. Thread the bearing retainer (key 136) into the body (key 142). Completely tighten the bearing retainer, and then loosen it one-quarter turn. Tighten the set screw (key 168, figure 16 or 17) to hold the bearing retainer in place.
4. Coat the groove in the handwheel body (key 142) with lithium grease (key 241). Insert the spring (key 56) and ball (key 55) into the handwheel (key 51). Holding the ball and spring in the handwheel, put the handwheel, the washer (key 149), the lockwasher (key 150), and the stop nut (key 54) onto the end of the end of the handwheel screw (key 145). Tighten the stop nut.
5. Position the pointer mounting bolt (key 159, not shown) and pointer (key 160). Insert and tighten the screw (key 161).
6. Assemble the two levers (key 146) with the cap screws (key 156) for handwheel assemblies for sizes 45/45i, 50/50i, and 60/60i actuators, or with the machine screws (key 156) for handwheel assemblies on sizes 34/34i and 40/40i actuators.
7. Use **step a.** for size 34 through size 60 actuators, and use **step b.** for sizes 34i through 60i.
 - a. **For Size 34 through 60:** If the handwheel assembly was removed from the yoke (key 9, figures 6, 8, or 10), remount the handjack assembly to the yoke using the dowel pins for alignment. For the size 34 and size 40, position the U-bolts and J-bolts (keys 166 and 143) on the yoke, and hand-tighten the hex nuts (keys 170 and 147) to hold the handwheel assembly in position. For the size 45 through size 60, position the U-bolts (keys 166 and 143) on the yoke, and hand-tighten the hex nuts (keys 170 and 144) to hold the handwheel assembly in position. Cap screws (key 163) should be tight against the yoke legs to provide stability. Tighten the nuts (key 144 for size 30 and size 40, key 158 for the size 45 through size 60). For the size 34 and size 40 finish tightening the U-bolt nuts to 81 N • m [60 lbf • ft] (key 170) and 41 N • m [30 lbf • ft] (key 147). For the sizes 45 through 60 finish tightening the U-bolt nuts to 163 N • m [120 lbf • ft] (key 170) and 41 N • m [30 lbf • ft] (key 144). Be sure the handwheel assembly remains flat against the mounting pad and perpendicular to the yoke.
 - b. **For Size 34i through 60i:** If the handwheel assembly was removed from the yoke (key 9, figures 7, 9, or 10), remount the handjack assembly to the yoke using the dowel pins for alignment. Position the upper cap screws (key 256) on the assembly and hand-tighten to hold the handwheel assembly in position. Place the spacers (key 258) between the yoke and handjack assembly, position cap screws (key 257), and hand-tighten. For the size 34i and size 40i finish tightening the cap screws (key 256) to 92 N • m [68 lbf • ft] and (key 257) to 39 N • m [29 lbf • ft]. For the sizes 45i through 60i finish tightening the cap screws (key 256) to 163 N • m [120 lbf • ft] and (key 257) to 39 N • m [29 lbf • ft].
8. Position the levers (key 146) as shown in figures 11 or 12. Insert the lever pivot pin (key 153), and snap the retaining ring (key 154) onto the lever pivot pin.

Side-Mounted Handwheel Assembly for Size 70, 76, and 87 Actuators

A side-mounted handwheel assembly (figure 20) is usually used as a manual actuator. Turning the handwheel clockwise past the neutral position always closes the valve body. A sleeve (key 123, figure 20) on a handwheel assembly for a size 70, 76 or 87 actuator opens the valve body by moving the valve stem.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; and then begin the assembly at the appropriate step.

Disassembly for Side-Mounted Handwheel (Sizes 70, 76, and 87)

1. Bypass the control valve. Reduce the loading pressure to atmospheric. Disconnect the loading pressure tubing or piping at the yoke.
2. Remove the cover band (key 87), and relieve spring compression by turning the spring adjuster (key 74) counterclockwise.
3. Remove the cap screws and nuts (keys 13 and 14) and lift off the upper diaphragm casing (key 1).
4. Remove the travel stop screw (key 12) and spacer (key 2), and take off the diaphragm plate (key 4), the diaphragm (key 3), and the lower diaphragm plate (key 71).
5. Unscrew the cap screws (key 90) and remove the following connected parts: the lower diaphragm casing (key 64), the O-ring (key 70), spring case adaptor (key 89), the seal bushing, O-rings, and snap ring (keys 7, 8, 9, and 72).
6. Remove the snap ring (key 72), and slide the seal bushing and O-rings (keys 7, 8, and 9) out of the spring case adaptor (key 89).
7. Take out the actuator spring (key 18).
8. Remove the stem connector (key 31) and stem connector cap screws.
9. Pull the actuator stem (key 144) up and out of the yoke. The spring seat (key 19), spring adjuster (key 74), thrust bearing (key 128), and the pinned adjusting screw (key 131) will come out with the actuator stem.
10. Turn the handwheel so that the lower sleeve (key 123) extends out of the bottom of the yoke. DO NOT move the neutral indicator scale (key 125).
11. Loosen two set screws (key 121), and unscrew the bearing retainer flange (key 45). Take out the worm gear and two thrust bearings (key 132), one on each side of the gear.
12. The worm shaft (key 51) and associated parts can be disassembled, if desired, by first removing the handwheel nut (key 127) and the handwheel (key 58). Do not lose the small ball (key 141) and spring (key 142).
13. Loosen the set screw (key 52) for each worm shaft retainer (keys 48 and 49). Unscrew the two worm retainers (keys 48 and 49). The ball bearings (key 50) will come out with the retainers.

Assembly for Side-Mounted Handwheel (Sizes 70, 76, and 87)

1. The front and back worm retainers (keys 48 and 49) each have a slot in their threads for a set screw (key 52). Pack the ball bearings (key 50) with anti-seize lubricant (key 239), and insert one ball bearing in the back worm retainer (key 49) as shown in figure 20.
2. Thread the back bearing retainer and ball bearing (keys 49 and 50) into the yoke. Align the slot in the bearing retainer with the set screw hole in the yoke, insert the set screw (key 52), and tighten it.
3. Coat the worm shaft (key 51) threads with anti-seize lubricant (key 239), and slide the shaft into the yoke so that the end of the shaft fits snugly into the back bearing retainer.
4. Insert the bearing in the front bearing retainer (key 49), and thread the retainer and ball bearing into the yoke. Align the slot in the retainer with the hole in the yoke, insert the set screw (key 52), and tighten it.
5. Put the spring and ball (keys 141 and 142) in the handwheel (key 58). Slide the handwheel onto the worm shaft (key 51). Thread the hex nut (key 127) onto the worm shaft.

6. Pack the two needle bearings (key 132) and coat the worm gear (key 44) threads with anti-seize lubricant (key 239). Insert the key (key 122), the bearings, and the worm gear in the yoke (key 73) as shown in figure 20.
7. Slots are cut in the threads of the bearing retainer flange (key 45). Thread the flange into the yoke so that the slots and the holes for the set screws (key 121) align. Insert the screws, and tighten them.
8. The lower sleeve (key 123) has a milled groove in one end. Coat the sleeve threads with anti-seize lubricant (key 239), slide the end of the lower sleeve with the groove into the bearing retainer flange, turn the handwheel, and feed the sleeve through the worm gear so that the slot in the lower sleeve engages the key (key 122) in the yoke. Continue turning the handwheel until the lower sleeve protrudes 81 mm (3.19 inches) below the surface of the yoke. The bottom of the lower sleeve should be even with the bottom of the extension on the neutral indicator.
9. Pack the thrust bearing (key 128) with anti-seize lubricant (key 239). Slide the actuator stem (key 144) and the attached adjusting screw (key 131), pin (key 130), thrust bearing (key 128), spring seat (key 19), and spring adjuster (key 74) into the yoke. The lower end of the stem slides through the lower sleeve (key 123) and the lower sleeve slides into the adjusting screw (key 131), as shown in figure 20.
10. Position the actuator stem (key 144) against the valve stem. Clamp both stems between the two halves of the stem connector (key 31), and be sure the threads are engaged properly on both stems. The stem connector should not be closer than 3.2 mm (1/8 inches) to the lower sleeve when the actuator stem is in the retracted position. This adjustment will provide approximately 3.2 mm (1/8 inches) of free travel of the lower sleeve in either direction for manual operation. Fasten the halves together with the cap screws.
11. Put the actuator spring (key 18) in the yoke on the spring seat (key 19).
12. Coat the O-rings (keys 8 and 9) with lithium grease (key 237), and insert them in the seal bushing (key 7). Slide the seal bushing and O-rings into the spring case adaptor (key 89).
13. Install the snap ring (key 72).
14. Slide the seal bushing and O-rings (keys 7, 8, and 9) over the actuator stem (key 144), and position the spring case adaptor (key 89), lower diaphragm casing (key 64), and O-ring (key 70) on the yoke.
15. Insert and tighten the cap screws (key 90).
16. Slide the lower diaphragm plate (key 71), the diaphragm (key 3) with the patterned side up, the diaphragm plate (key 4), the spacer (key 2), and the cap screw (key 12) on the actuator stem (key 144). Tighten the cap screw.
17. Put the diaphragm casing (key 1) on the diaphragm. Align the holes in the diaphragm (key 3) and the diaphragm casings (keys 1 and 64).

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 30/30i-76/76i and 87 actuators.

CAUTION

Over-tightening the diaphragm cap screws and nuts (keys 13 and 14) can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

18. Install the cap screws and hex nuts (keys 13 and 14) and tighten in the following manner.

19. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 13 N•m (10 lbf•ft).
20. Tighten the remaining bolts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
21. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
22. Tighten the remaining bolts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
23. After the last bolt is tightened to 27 N•m (20 lbf•ft), all of the bolts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
24. Once completed, no more tightening is recommended.
25. Return the actuator to service after completing the Loading Connection procedure in the Installation section and the procedures in the Adjustments section.

Casing-Mounted Travel Stops

Note

If repeated or daily manual operation is expected, the actuator should be equipped with a side-mounted handwheel rather than a casing-mounted travel stop or top-mounted handwheel. The side-mounted handwheel is designed for more frequent use as manual operator.

Casing-mounted adjustable travel stops (shown in figures 21 through 25) are available to limit travel in the down direction (extending the actuator stem) or in the up direction (retracting the actuator stem). The travel stop in figure 21 is a down travel stop, the travel stop in figure 22 is an up and down travel stop, and the travel stops in figures 23, 24, and 25 are up travel stops.

Use the locknuts (key 151, figures 21 and 22), stem (key 150, figure 23), handwheel (key 58, figure 24) or cap screw (key 177, figure 25) to set the point at which the travel stop limits travel. Be sure to tighten the locknuts and replace the cap (key 149, figures 21 and 23; key 247, figure 22) after setting the travel stop.

Instructions are given below for disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Key numbers are shown in figures 21 through 25.

1. Remove the cap (key 149 or 247) if the travel stop uses one. For down travel stops, loosen the locknuts (key 151, figures 21 and 22) so that the stop is not causing any spring compression.
2. Bypass the control valve, reduce loading pressure to atmospheric, and remove the tubing or piping from the connection on top of the yoke (key 73, figures 6, 8, and 10).
3. For down travel stops, turn the spring adjuster (key 74, figures 6, 8, and 10) out of the yoke toward the stem connector (key 31) to relieve all the compression in the spring (key 18).
4. For style 11 travel stops (figure 22), unscrew the cap screws (key 161), and make sure that the guide plate (key 157) can turn between the handwheel body (key 148) and the mounting plate (key 158).
5. Use a wrench on the nuts (key 151) to unscrew the extension rod (key 150). Remove the rod, the handwheel body (key 148), and the attached parts.
6. Unscrew the hex nuts and cap screws (keys 14 and 13, figures 6, 8, and 10) from the diaphragm casings. Lift off the upper diaphragm casing (key 1, figures 6, 8, and 10) and, for the style 11 travel stop, the mounting plate (key 158). For styles 10, 12 and 13, the travel stop assembly will be removed with the casing.
7. Note and record the position of travel stops (key 152) relative to the cap screws (key 154) for use in assembly. Unscrew the travel stops and cap screws, and remove either the mounting plate (key 158) or the handwheel body (key 148) and attached parts.

8. Separate the stem (key 150) and screw (key 160, figure 22) from the handwheel body.
9. Before reassembling, lubricate parts indicated by key 239 in figures 21 through 25. Use anti-seize lubricant (key 239).
10. Reassemble parts in the reverse order of removal.
11. When replacing the cap screws (key 154) and, if used, the travel stops (key 152), be sure to return them to their original position as recorded in step 7.

CAUTION

Over-tightening the diaphragm cap screws and nuts (keys 13 and 14), figures 6, 7, 8, 9, and 10 can damage the diaphragm. Do not exceed 27 N•m (20 lbf•ft) torque.

12. Install the cap screws and nuts (keys 13 and 14, figures 6, 7, 8, 9, and 10) and finger tighten. Tighten the diaphragm cap screws and nuts to 27 N•m (20 lbf•ft) torque in a crisscross pattern.
13. Return the spring adjuster (key 74, figure 6, 7, 8, 9, and 10) to its original position. Re-adjust the travel stop.

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always mention this number when corresponding with your [Emerson sales office](#) or Local Business Partner regarding technical information or replacement parts. Also, reference the complete 11-character part number of each needed part as found in the following Parts Kits and Parts List sections.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts Kits

Actuator Repair — Soft Parts Kits

Parts kit includes keys 8, 9, and 70. O-ring material is nitrile, and gasket material is composition.

Description	Part Number
Size 30/30i	R667X000302
Sizes 34/34i & 40/40i	R667X000402
Sizes 45/45i through 60/60i	R667X000502
Sizes 70/70i & 87	R667X000702
Size 76/76i	R667X000762

Actuator Repair — Hardware Kits

Hardware kit includes casing bolts (key 13), casing nuts (key 14), actuator stem (key 144), and seal bushing (key 7) in standard materials.

Description	Part Number
Size 30/30i	R667X000312
Size 34/34i	R667X000412
Size 40/40i	R667X000422
Size 45/45i	R667X000512
Size 46/46i	R667X000522
Size 50/50i	R667X000532
Size 60/60i	R667X000542
Size 70/70i	R667X000722

Size 87	R667X000732

Side-Mounted Handwheels Retrofit Kits

Retrofit Kit includes parts to add a Side-Mounted Handwheel.

Description	Part Number
Size 34 Push-Down-To-Close	30A8778X0E2
Size 34 Push-Down-To-Open	30A8778X0F2
Size 40 Push-Down-To-Close	30A8778X0G2
Size 40 Push-Down-To-Open	30A8778X0H2
Size 45 & 46 Push-Down-To-Close	40A8779X0A2
Size 45 & 46 Push-Down-To-Open	40A8779X0B2
Size 50 & 60 Push-Down-To-Close	40A8779X0C2
Size 50 & 60 Push-Down-To-Open	40A8779X0D2
Size 34i push down to close	GE71635X0E2
Size 34i push down to open	GE71635X0F2
Size 40i push down to close	GE71635X0G2
Size 40i push down to open	GE71635X0H2
Size 45i & 46i push down to close	GE71636X0A2
Size 40i & 60i push down to open	GE71636X0B2
Size 50i & 60i push down to close	GE71636X0C2
Size 50i & 60i push down to open	GE71636X0D2

Top-Mounted Handwheels Retrofit Kits

Retrofit Kit includes parts to add a Top-Mounted Handwheel.

Kit number 1 includes the handwheel assembly only.

Kit number 2 includes Kit number 1 and a new diaphragm case that is required to mount the handwheel assembly.

Description	Part Number
Kit 1	
Size 30/30i	30B3940X102
Sizes 34/34i	30B3940X022
Size 40/40i	30B3940X042
Sizes 45/45i & 50/50i	33B9224X012
Sizes 46/46i, 60/60i, & 76/76i	33B9224X012
Sizes 70/70i & 87	CV8060X0012
Kit 2	
Size 30/30i	30B3940X052
Size 34/34i	30B3940X062
Size 40/40i	30B3940X092
Sizes 45/45i & 50/50i	33B9224X022
Sizes 46/46i, 60/60i, & 76/76i	33B9224X032
Sizes 70/70i & 87	CV8060X0022

Transition Kits for Side-Mounted Handwheels

Transition kits include fasteners necessary to remount an existing side-mounted handwheel to an actuator where the yoke has been changed to a size i yoke.

Contains key numbers 256, 257, and 258.

Description	Part Number
Size 34i/40i push-down-to-close or push-down-to-open	GE71635X0J2
Size 45i - 60i push-down-to-close or push-down-to-open	GE71636X0E2

Introduction

Scope of Manual

This instruction manual provides information on installation, adjustment, maintenance, and parts ordering for the Fisher 667 actuator in sizes 80 and 100 (figure 1). Refer to separate instruction manuals for information about other equipment and accessories used with these actuators.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

667 Size 80 and 100 Actuators

July 2023

Instruction Manual

D100311X012

Do not install, operate, or maintain 667 actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

1. Heavy actuator-to-bonnet bolting.					

1. Heavy actuator-to-bonnet bolting.

Description

The 667 actuator is a reverse-acting actuator. Reverse-acting actuators use air action to lift the diaphragm (away from the valve), and spring action opposes the diaphragm action (see figure 2). The actuator position changes in response to varying controlled air pressure to the diaphragm. If air pressure is reduced or lost from the actuator diaphragm, spring action will extend the actuator stem. The actuator is often used with control valves using a pneumatic positioner for air pressure control, and where fail action will fully open or close the control valve as the actuator stem extends.

Also, the actuator can be furnished with either a side-mounted (size 80 only) handwheel assembly or a top-mounted handwheel (adjustable up travel stop) (size 100 only). The size 80 side-mounted handwheel is normally used as an auxiliary manual actuator. The size 100 top-mounted handwheel is used as either a travel stop or an auxiliary manual actuator.

The actuator can be furnished with a top-loading capability. A top-loaded actuator allows air pressure to be applied to the top of the diaphragm, aiding the spring to extend the actuator stem. This air pressure increases valve seat load on valve applications where additional seat-loading is necessary.

Specifications

Refer to table 1 for Specifications of the 667 actuator. See the actuator nameplate for information about a specific actuator.

Figure 2. Schematic Representation of Fisher 667 Actuator

667 REVERSE-ACTING DIAPHRAGM ACTUATOR

Table 2. Maximum Pressure Limitations

PRESSURE LIMITATIONS		ACTUATOR SIZE		
		80		100
		Standard Cast Iron Construction	All Steel Construction	
Maximum Casing Pressure for Actuator Sizing	bar	3.4	4.9	6.9
	psig	50	70	100
Maximum Excess Diaphragm Pressure	bar	1.4	1.4	1.7
	psig	20	20	25
Maximum Diaphragm Casing Pressure		Upper bench set plus Maximum Excess Diaphragm Pressure or 4.1 bar (60 psig), whichever is less.	Upper bench set plus Maximum Excess Diaphragm Pressure or 5.5 bar (80 psig), whichever is less.	Upper bench set plus Maximum Excess Diaphragm Pressure or 7.9 bar (115 psig), whichever is less.

Maximum Pressure Limitations

⚠ WARNING

To avoid personal injury or parts damage, do not apply pressure that exceeds the Maximum Pressures listed in table 2. Exceeding any of the maximum pressures can result in uncontrolled movement of parts, damage to actuator parts and the control valve, and loss of control of the process. Use pressure-limiting or pressure-relieving devices to prevent casing pressure from exceeding these limits.

Do not apply a pressure that produces a force on the actuator stem greater than the maximum allowable actuator output thrust or the maximum allowable stem load.

The casing and diaphragm of 667 actuators are pressure operated. This air pressure provides force to compress the spring and stroke the actuator. The following explanations describe the maximum pressure limits for 667 actuators. Refer to the nameplate, warning tag, and table 2 for maximum values.

- **Maximum Casing Pressure for Actuator Sizing:** This is the maximum pressure that can be applied to provide full travel of the actuator. If this stroking pressure is exceeded before the upper diaphragm plate contacts the travel stop, damage to the stem or other parts might result. The Maximum Diaphragm Casing Pressure for a specific actuator construction may be less than the Maximum Casing Pressure for Actuator Sizing. See table 2.
- **Maximum Excess Diaphragm Pressure:** This is the additional pressure that may be added when the actuator is at full travel. If the Maximum Excess Diaphragm Pressure is exceeded once the actuator has reached full travel, damage to the diaphragm or diaphragm casing might result.

Because the actuator has traveled its specified travel, and the diaphragm head is physically stopped from movement, the force from any additional air pressure is transmitted to the diaphragm and diaphragm casings. The amount of air pressure that can be added once the actuator has traveled to the stops is limited by the resultant adverse effects that may occur. Exceeding this limiting factor could result in leakage or casing fatigue due to the deformation of the upper diaphragm casing.

- **Maximum Diaphragm Casing Pressure:** If the Maximum Diaphragm Casing Pressure is exceeded, damage to the diaphragm, diaphragm casing, or actuator might result. For some actuator constructions, the maximum Diaphragm Casing Pressure is the sum of the upper bench set, noted on the nameplate, added to the Maximum Excess Diaphragm Pressure. For other actuator sizes, the value is lower, see table 2.

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

When an actuator and valve are shipped together, the actuator is normally mounted on the valve. Follow the valve instructions when installing the control valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the following Actuator Mounting procedures.

For information on mounting valve positioners, refer to the appropriate valve positioner instruction manual.

Actuator Mounting

1. Mount the actuator on the valve bonnet. Insert the cap screws and tighten the hex nuts, securing the actuator to the bonnet.
2. Screw the valve stem jam nuts (key 69, figures 6 and 7) all the way onto the valve stem threads.
3. Connect an air supply to the lower diaphragm casing connection.
4. For push-down-to-close valves, be sure the valve plug is on its seat. Reduce loading pressure to ensure that the actuator stem is fully extended. Apply slight loading pressure to retract the stem approximately 3.2 mm (1/8-inch).

5. For push-down-to-open valves, apply pressure to ensure that the actuator stem is fully retracted. Be sure the valve plug is on its seat. On large valve sizes, this may require the use of a pry bar inserted through the valve body line opening. If the valve is installed in a pipeline, the bottom flange (if one is used) can be removed and the valve plug pushed to the seat from the bottom opening. Reduce actuator loading pressure to extend the stem approximately 3.2 mm (1/8-inch).

NOTICE

Incomplete engagement of either the valve stem or actuator stem in the stem connector can result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than the diameter of that stem.

6. Clamp the actuator and valve plug stems between the two stem connector halves (key 31, figures 6 and 7). Insert and tighten the stem connector cap screws.
7. Thread the stem locknuts against the stem connector.
8. Align the travel indicator scale (key 32, figures 6 and 7) to show valve position.

⚠ WARNING

To avoid personal injury due to the sudden, uncontrolled movement of parts, do not loosen the cap screws when the stem connector has spring or loading pressure force applied to it.

Loading Connection

Key number locations are shown in figures 6 and 7, unless otherwise directed.

1. Connect the loading pressure piping to the connection in the size 80 spring case adaptor (key 89) or in the size 100 lower diaphragm casing (key 67).

For top-loaded actuators

1. For size 80, remove the the pipe bushing (key 78), and connect the loading pressure piping in its place. For size 100, remove the hex bushing (key 62) from the upper casing (key 1), and connect the top loading pressure piping in its place.
2. Remove the 1/4-inch bushing (key 92, figure 6; key 62, figure 7) to increase connection size, if necessary. The connection can be made with either piping or tubing.
3. Keep the length of tubing or piping as short as possible to avoid transmission lag in the control signal. If an accessory (such as a volume booster or valve positioner) is used, be sure that the accessory is properly connected to the actuator. Refer to the positioner instruction manual as necessary.
4. Cycle the actuator several times to check that the valve stem travel is correct and that the travel occurs when the correct pressure range is applied to the diaphragm.
5. If valve stem travel is incorrect, refer to the Travel procedure in the Adjustments section.
6. If the spring pressure range is incorrect, refer to the Spring procedure in the Adjustments section.

Adjustments

Travel

Make travel adjustments when the motion observed during actuator travel is different from the travel stamped on the actuator nameplate. If the Actuator Mounting procedure was followed correctly, this adjustment should not be necessary.

When adjusting travel of a direct-acting valve, put a slight pressure on the actuator diaphragm. This moves the valve plug off the seat, reducing the chance of damaging the valve plug or seat during adjustments.

1. Back the stem jam nuts (key 69, figures 6 and 7) away from the stem connector (key 31, figures 6 and 7), and slightly loosen the stem connector cap screws.

NOTICE

Do not use wrenches or other tools directly on the valve stem. Damage to the stem surface and subsequent damage to the valve packing may result.

2. Tighten the locknuts together, using a wrench, then screw the valve stem either into the stem connector to lengthen travel or out of the stem connector to shorten travel.
3. Cycle the actuator to check for the specified travel. If actual travel is not equal to the specified travel, adjust and check travel until correct. Tighten the stem connector cap screws when correct travel is obtained.
4. Raise the travel indicator disk by threading the stem locknuts against the stem connector.

Spring

Make spring adjustments when the loading pressure range applied to achieve specified travel is not equal to the pressure range stamped on the actuator nameplate. Refer to the Bench Set pressure range on the nameplate when the valve contains no pressure and the packing is loosely inserted in the bonnet. Refer to the Maximum Allowable Supply pressure on the nameplate when the valve is controlling the specified pressure drop, and the packing is tightened to stop leaks around the stem.

Monitor loading pressure carefully when making adjustments. Do not exceed the pressure specifications of either the loading regulator or the actuator casings.

Each actuator spring has a fixed pressure span. Changing the spring compression shifts the span up or down to make valve travel coincide with the loading pressure range.

Size 80 Actuator Spring

Note

Before turning the spring adjuster on size 80 actuators, assemble the stem connector around the actuator stem and the anti-rotating lug on the yoke. Mark the actuator stem as a visual reference to verify that stem rotation does not occur. Remove the stem connector before rechecking the bench set.

Remove the cover band (key 87, figure 6), insert a rod of approximately 12.7 mm (1/2 inch) diameter into a hole in the spring adjuster (key 74, figure 6), and rotate the spring adjuster with the rod. Rotating the adjuster from left to right will increase the loading pressure required to start actuator stem travel; opposite rotation will decrease the pressure required to start travel.

Size 100 Actuator Spring

NOTICE

The actuator must be in the vertical position when adjusting the spring to avoid damage to the thrust bearing (key 86, figure 7) and to properly position the spacers required for adjustment.

Remove the shroud plate (key 65, figure 7), and loosen the jam nut (key 26, figure 7).

For small spring forces, adjustments can be made by rotating the adjusting nut (key 25, figure 7). Counterclockwise rotation (when viewed from the diaphragm casings) of the adjusting nut will increase the loading pressure required to start actuator stem travel, and clockwise rotation will decrease the pressure required to start travel. Tighten the jam nut when adjustment is complete.

For high spring forces, it is necessary to use spacers between the bottom of the yoke and the spring seat to isolate spring force from the adjusting nut.

⚠ WARNING

To avoid personal injury from the compressed actuator spring snapping back to its original length, make and use the spacers by following the instructions in the steps below.

1. It is recommended that three spacers be made of three-inch schedule 80 pipe cut to the appropriate length specified in step 2. If other than the recommended material is to be used, be certain that the spacers are capable of withstanding the spring force involved. The spacers must also be of equal length with ends cut squarely.
2. Measure dimension B as shown in figure 3. Cut the length of the spacers as follows:
 - a. If it is desired to decrease spring compression, make the spacers approximately 4.8 mm (3/16-inch) longer than dimension B.
 - b. If it is desired to increase spring compression, make the spacers approximately 4.8 mm (3/16-inch) shorter than either dimension B plus the amount of adjustment required or dimension B plus valve travel, whichever is less.
3. Whenever the total amount of adjustment required is greater than valve travel, the adjustment must be made in two or more steps, and the amount of adjustment taken in each step must be less than valve travel.
4. Pressure the actuator to attain full travel. Cautiously insert the spacers at equal intervals around the spring seat (key 19, figure 7). Spacers must be seated squarely, or they may slip out of position. Keeping hands and tools away from the spring and spring seat, slowly decrease loading pressure until the spring force holds the spacers firmly between the spring seat and the bottom of the yoke.
5. Loosen the jam nut. The adjusting nut can now be rotated counterclockwise (when viewed from the diaphragm casings) to increase the loading pressure required to start actuator stem travel or clockwise to decrease the pressure required to start travel.
6. Pressure the actuator to move the spring seat away from the spacers, and carefully remove the spacers.
7. Slowly reduce the air pressure to the actuator. Make sure that the thrust bearing (key 86) is correctly seated in the spring seat before contact with the adjustment nut (key 25) is made.
8. If the total adjustment required was greater than valve travel, repeat the procedure. It will be necessary to make new spacers using the new dimension B and the remaining adjustment required or valve travel, whichever is less. Tighten the jam nut when adjustment is complete.

Maintenance

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Figure 3. Dimension B for Spring Adjustment

Size 80 Actuator Maintenance

For size 80 actuators, refer to figure 4 for part names and locations. Key number locations for size 80 actuators are shown in figure 6.

Disassembly

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve, and drain the process media from both sides of the valve. Shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

2. Remove the tubing or piping from the connection in the top of the spring case adaptor (key 89).
3. If the actuator has a handwheel, rotate the handwheel to relieve all spring compression.
4. Remove the cover band (key 87). Insert a steel rod of approximately 12.7 mm (1/2-inch) diameter into a hole in the spring adjustor (key 74), and rotate the spring adjustor from right to left until spring compression is relieved.

⚠ WARNING

To avoid personal injury due to the sudden, uncontrolled movement of parts, do not loosen the cap screws on the stem connector (key 31) when spring force is applied.

5. If necessary, the entire actuator assembly may be removed from the valve by unscrewing the cap screws from the stem connector (key 31) and removing actuator-to-bonnet bolting.
6. Unscrew the diaphragm casing cap screws and nuts (keys 13 and 14), and lift off the upper diaphragm casing (key 1).
7. Unscrew the diaphragm cap screw (key 12), remove the spacer, upper diaphragm plate, diaphragm, and lower diaphragm plate (keys 2, 4, 3, and 71).

Note

Standard and top-loaded constructions use the same key numbers for parts. The parts look different, but they use the same assembly and disassembly sequence. See figure 4, Size 80 Actuator Construction for location of parts.

8. Unscrew the cap screws (key 30), and remove the lower diaphragm casing (key 64).
9. For actuators without a snubber:
 - a. Unscrew the spring case adaptor cap screws and nuts (keys 90 and 91), and remove the adaptor (key 89) from the actuator.
 - b. Remove the snap ring and seal bushings (keys 72 and 7). Inspect, and if necessary, obtain a replacement seal bushing (key 7). Replace the seal bushing O-rings (keys 8 and 9) as required. Lubricate with lithium grease (key 237) lubricant.
 - c. Remove the actuator spring (key 18). Unscrew the cap screws from the stem connector (key 31), and remove the stem connector. Remove the stem (key 144) and attached spring adjustor, thrust bearing, and spring seat (keys 74, 86, and 19).
10. For actuators with a snubber (see figure 8):

⚠ WARNING

To avoid personal injury due to the sudden, uncontrolled movement of parts, ensure the actuator spring is not under compression before removing the travel stop.

- a. Remove the travel stop (key 84). Be certain there is not compression in the actuator spring (key 18). If the actuator was removed from the valve, secure the stem connector (key 31) to the actuator stem (key 144) to prevent the stem from turning while unscrewing the stem and piston assembly (key 23).
- b. Using a wrench on the wrench flats near the top of the stem and piston assembly, unscrew the stem and piston assembly from the actuator stem.

- c. Unscrew the cap screws (key 106), and remove the cylinder (key 93) and attached parts.

11. To disassemble snubber:

- a. Remove the retaining rings, cylinder heads, and stem and piston assembly (keys 95, 94, and 23).
- b. Replace packing and O-rings (keys 118, 119, 96, 107, and 120).
- c. Unscrew the spring case adaptor cap screws and nuts (keys 90 and 91), and remove the adaptor (key 89) from the actuator.

12. Remove the actuator spring and spring seat (keys 18 and 19).

13. Unscrew the cap screws and nuts (keys 88 and 91), and remove the spring case (key 85).

Note

In figure 8, the cap screws (key 88) on units with side-mounted handwheels do not use hex nuts (key 91).

14. Remove the spring adjustor (key 74) and the attached thrust bearing (key 86).

15. Remove the cap screws (key 252), yoke bushing retainer (key 251), 2 halves of the split yoke bushing (key 249), and yoke bushing holder (key 250).

16. Refer to the size 80 actuator assembly procedures. Carefully clean and inspect all parts, and obtain any replacement parts required for reassembly.

Assembly

See figure 4, Size 80 Actuator Construction for location of parts.

- 1. Coat the threads of the stem (key 144) with lithium grease lubricant (key 237). Install the spring adjustor (key 74) and thrust bearing. Pack the bearing (key 86) with lithium grease lubricant.
- 2. Mount the spring case (key 85) to the yoke (key 73) using cap screws and hex nuts (keys 88 and 91).

Note

Units with a side-mounted handwheel do not use hex nuts (key 91).

3. Install the spring adjustor, thrust bearing, and spring seat (keys 74, 86 and 19) onto the actuator stem (key 144). Slide the stem into the spring case (key 85).

4. Align the spring seat (key 19) on the spring adjustor (key 74), and slide the actuator spring (key 18) squarely onto the spring seat.

5. Mount the spring case adaptor (key 89) to the spring case (key 85) using cap screws and hex nuts (keys 90 and 91).

6. For actuators with a snubber (see figure 8), install the cylinder (key 93) and attached parts with cap screws (key 106). Slide the stem and piston assembly (key 23) into the cylinder and thread onto the actuator stem (key 144). Attach the travel stop (key 84), if one is used, to the stem and piston assembly.

Figure 4. Size 80 Actuator Construction

- For actuators without a snubber, install the seal bushing (key 7) into the spring case adaptor (key 89) followed by the snap ring (key 72). Replace the seal bushing O-rings (keys 8 and 9) as required.
- Coat the gasket (key 70) with lithium grease lubricant (key 237). Position the lower diaphragm casing (key 64) on the spring case adaptor, and secure with cap screws (key 30).
- Mount the lower diaphragm plate, diaphragm, upper diaphragm plate, and, if used, spacer (keys 71, 3, 4, and 2) on the actuator stem (key 144), and secure using the cap screw (key 12). Coat the cap screw threads with lithium grease (key 237). Tighten the cap screw (key 12) to 544 N•m (400 lbf•ft).

Note

Standard and top-loaded constructions use the same key numbers for parts. The parts look different, but they use the same assembly and disassembly sequence. See figure 4, Size 80 Actuator Construction.

10. Position the upper diaphragm casing (key 1) on the diaphragm (key 3), and align the holes.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing cap screws are tightened to the proper load to prevent leakage, but do not crush the material. Perform the following tightening sequence with a manual torque wrench for size 80 and 100 actuators.

NOTICE

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

Overtightening the diaphragm casing cap screws and nuts can damage the diaphragm. Do not exceed the following maximum torque values for the appropriate diaphragm material: EPDM/Meta-Aramid: 95 N•m (70 lbf•ft); Nitrile, Silicone, FKM (fluorocarbon) / Meta-Aramid: 68 N•m (50 lbf•ft).

11. Insert the cap screws (key 13) into the diaphragm casing, and tighten the hex nuts (key 23) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to the initial torque value found in table 3 for the diaphragm material being used.
12. Tighten the remaining hex nuts in a clockwise, crisscross pattern to the initial torque value found in table 3 for the diaphragm material being used.
13. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to the final torque value that is specified in table 3 for the diaphragm material being used.
14. Tighten the remaining hex nuts in a clockwise, crisscross pattern to the final torque value that is specified in table 3 for the diaphragm material being used.
15. After the last hex nut is tightened, complete another tightening sequence. Tighten in a circular pattern around the bolt circle to the final torque value that is specified in table 3 for the diaphragm material being used.
16. Once completed, no more tightening is recommended.
17. For size 80 actuators without a manual operator, slide the following parts over the bottom of the stem; yoke bushing holder (key 250), two split yoke bushings (key 249), and yoke bushing retainer (key 251). Secure into place with 4 cap screws (key 252). Before inserting the bushing halves, lightly coat with lithium grease (key 237) lubricant.
18. Mount the actuator on the valve in accordance with the procedures in the Installation section.

Size 100 Actuator Maintenance

For size 100 actuators, refer to figure 5 for part names and locations. Key number locations for Size 100 actuators are shown in figure 7.

Table 3. Size 80 Casing Cap Screw Torque Values

DIAPHRAGM MATERIAL	INITIAL TORQUE	FINAL TORQUE
	N•m (lbf•ft)	N•m (lbf•ft)
EPDM / Meta-Aramid	41 (30)	82 ± 13 (60 ± 10)
Nitrile, Silicone, FKM/Meta-Aramid	34 (25)	68 (50)

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, release all air pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. Remove the shroud plate (key 65) by removing the cap head screws (key 66).
 - a. For small spring force, loosen the jam nut (key 26), and rotate the adjusting nut (key 25) until spring compression is relieved.
 - b. For high spring force:

Note

To relieve spring compression when high spring forces exist, refer to the Spring section, and follow the instructions given for size 100 actuators with high spring force. These instructions outline the procedure required to decrease high spring compression.

Loosen the jam nut (key 26), and rotate the adjusting nut (key 25) until spring compression is relieved.

3. Remove the pressure tubing or piping from the top of the diaphragm casing.
4. For actuators with a top-mounted handwheel (see figure 9), rotate the handwheel (key 58) clockwise as far as it will go, unscrew the cap screws (key 54), and remove the gear case cover (key 53). Remove the travel stop cap screw, if one is used, from the actuator stem extension (key 36), and unscrew the hex nuts (key 47). Unscrew the cap screws that attach the gear case assembly (key 41) to the actuator, and remove the gear case assembly.
5. If necessary, remove the actuator from the valve by separating the stem connector (key 31) and removing the actuator-to-bonnet bolting. Separate the stem connector by loosening the stem locknuts (key 69) and unscrewing the four cap screws.

Note

If the actuator has been removed from the valve, ensure that it is in the vertical position. Then, block the actuator stem (key 144) to support the weight of the actuator stem, spring seat and spring (keys 144, 19, and 18). This will facilitate removal of the nut (key 24) or actuator stem connector (key 31, figure 8).

Figure 5. Size 100 Actuator Construction

50A2623-F

STANDARD DIAPHRAGM CONSTRUCTION

56A9820-B
C0773-1

TOP LOADED DIAPHRAGM CONSTRUCTION

For Actuators Without the Top-Loaded Option

Disassembly

Part names and locations are shown in figure 5. Size 100 actuator key number locations are shown in figure 7.

1. Unscrew the diaphragm casing cap screws and nuts (keys 13 and 14) and remove the upper diaphragm casing.
2. For actuators without a top-mounted handwheel, unscrew and remove the travel stop cap screw (key 12), if one is used, and the hex nut (key 24).
3. For actuators with a top-mounted handwheel (see figure 9), remove the hex nut, actuator stem extension, and actuator stem connector (keys 28, 36, and 42).
4. Remove the washer, upper diaphragm plate, diaphragm, diaphragm retainer, and backup plate (keys 37, 4, 3, 5 and 6).
5. Unscrew the six cap screws (key 11), and remove the seal bushing retainer (key 10). Remove the seal bushing (key 7).

⚠ WARNING

To avoid personal injury and property damage from the sudden release of spring load, be sure that all spring load is removed from the actuator lower diaphragm casing.

6. Unscrew the four hex nuts that secure the lower diaphragm casing to the yoke assembly (key 67), and remove the lower diaphragm casing. Replace the yoke assembly O-rings (key 70) as necessary.
7. The actuator spring (key 18) and stem (key 144) can now be removed if necessary. Be sure to disconnect the stem connector (key 31) before removing the stem.
8. Refer to the following Assembly procedures. Carefully clean and inspect all parts, or obtain replacement parts required for reassembly.

Assembly

1. If the actuator stem (key 144, figure 7) was removed, lubricate the threads on the stem with lithium grease lubricant (key 237).
2. On the actuator stem, assemble the hex nuts, thrust bearing, and spring seat (keys 26, 25, 86, and 19) to the stem. Be certain that the thrust bearing race with the larger inside diameter faces the spring seat. Rotate the adjusting nut (key 25) to position the spring seat 305 mm (12 inches) from the end of the stem.
3. Install the actuator stem assembly into the yoke assembly (key 67). Place a support under the stem to position the lower end of the stem 254 mm (10 inches) above the bottom surface of the actuator (actuator-to-bonnet joint).

Note

When installing lower diaphragm casing, install the O-rings (key 70) into the grooves found in the lower diaphragm casing before placing the casing on the yoke assembly. If the spring interferes with installation of the lower diaphragm casing, reposition the spring by rotating the adjusting nut (key 25).

4. Install the lower diaphragm casing, and secure it by tightening the four hex nuts.
5. Lubricate the seal bushing O-rings (keys 8 and 9) and the seal bushing (key 7) with lithium grease lubricant. Install the seal bushing O-rings, seal bushing, and seal bushing retainer (keys 8, 9, 7 and 10) and secure with the cap screws (key 11).

6. Install the diaphragm backup plate, diaphragm retainer, diaphragm, upper diaphragm plate, and washer (keys 6, 5, 3, 4, and 37) on the actuator stem (key 144).

NOTICE

Install the diaphragm with the fabric side facing away from the spring. Smooth the edge of the diaphragm to avoid wrinkling and be careful that the diaphragm fold does not get pinched when the upper diaphragm casing (key 1) is installed.

NOTICE

If the diaphragm (key 3) is installed so air pressure is applied to the fabric side, it will immediately delaminate the sealing surface (smooth surface) from the fabric. The delamination can cause immediate failure of the diaphragm's ability to retain pressure.

7. For actuators with a top-mounted handwheel, screw the actuator stem extension (key 36, figure 9) as far as it will go into the actuator stem connector (key 42, figure 9) before tightening the hex nut (key 28, figure 9).
8. For actuators without a top-mounted handwheel, install the hex nut (key 241) and tighten, install the jam nut (key 24) and tighten so that it locks the hex nut key 24 in place. Install the travel stop (key 12).
9. Position the upper diaphragm casing (key 1) on the diaphragm (key 3) and align the holes.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing cap screws are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 80 and 100 actuators.

NOTICE

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

Overtightening the diaphragm casing cap screws and nuts can damage the diaphragm. Do not exceed 68 N•m (50 lbf•ft) torque.

10. Insert the cap screws (key 13) into the upper diaphragm casing, and tighten the hex nuts (key 14) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to 34 N•m (25 lbf•ft).
11. Tighten the remaining hex nuts in a clockwise, crisscross pattern to 34 N•m (25 lbf•ft).
12. Repeat this procedure by tightening the four hex nuts, diametrically opposed and 90 degrees apart, to a torque of 68 N•m (50 lbf•ft).
13. Tighten the remaining hex nuts in a clockwise, crisscross pattern to 68 N•m (50 lbf•ft).
14. After the last hex nut is tightened to 68 N•m (50 lbf•ft), all of the hex nuts should be tightened again to 68 N•m (50 lbf•ft) in a circular pattern around the bolt circle.

15. Once completed, no more tightening is recommended.
16. For actuators with a top-mounted handwheel (see figure 9), mount the gear case assembly (key 41) on the actuator using the cap screws (key 16). Install the hex nuts (key 47) and travel stop cap screw (if used) on the actuator stem extension (key 36). Install the gear case cover (key 53) with the cap screws (key 54).
17. Mount the actuator on the valve, and secure with the actuator-to-bonnet bolting. Refer to the Installation section to connect the actuator stem to the valve plug stem.

For Actuators With the Top-Loaded Option

Disassembly

For key number locations refer to figure 7, and refer to the Top-Loaded Actuator Detail shown in figure 7. Also, refer to figure 5 for diaphragm construction details.

1. Remove the 40 cap screws (key 13) from the upper diaphragm casing (key 1) and remove the casing.
2. Remove the travel stop cap screw (key 12), hex nuts (key 24 and 241), washer (key 37), backup plate (key 6), diaphragm retainer (key 5), diaphragm (key 3), and diaphragm backup plate (key 246) with O-ring (key 240).
3. Remove the 40 cap screws (key 13) from the lower side of the casing adaptor (key 245) and remove the adapter.
4. Remove the diaphragm plate (key 4) with O-ring (key 240), diaphragm (key 3), diaphragm retainer (key 5), and backup plate (key 6).
5. Unscrew the six cap screws (key 11) and remove the seal bushing retainer (key 10). Remove the seal bushing (key 7). Remove and replace the seal bushing O-rings (keys 8 and 9) as necessary.

⚠ WARNING

To avoid personal injury due to the sudden, uncontrolled movement of parts, do not loosen the four hex nuts on the lower diaphragm casing when spring pressure is applied. Ensure that all spring precompression has been released.

6. Unscrew the four hex nuts that secure the lower diaphragm casing to the yoke assembly (key 67) and remove the lower diaphragm casing. Replace the yoke assembly O-rings (key 70) as necessary.
7. The actuator spring (key 18) and stem (key 144) can now be removed if necessary. Be sure to disconnect the stem connector (key 31) before removing the stem.
8. Unscrew the six cap screws (key 11) and remove the seal bushing retainer (key 10). Remove the seal bushing (key 7). Remove and replace the seal bushing O-rings (keys 8 and 9) as necessary.
9. Unscrew the four hex nuts that secure the lower diaphragm casing to the yoke assembly (key 67) and remove the lower diaphragm casing. Replace the yoke assembly O-rings (key 70) as necessary.
10. The actuator spring (key 18) and stem (key 144) can now be removed if necessary. Be sure to disconnect the stem connector (key 31) before removing the stem.
11. Refer to the size 100 actuator assembly procedures. Carefully clean and inspect all parts, and obtain any replacement parts required for reassembly.

Assembly

1. If the actuator stem (key 144) was removed, lubricate the threads on the stem with lithium grease lubricant (key 237).
2. Assemble the hex nuts, thrust bearing, and spring seat (keys 26, 25, 86, and 19) to the stem. Be certain that the thrust bearing race with the larger inside diameter faces the spring seat. Rotate the adjusting nut (key 25) to position the spring seat 305 mm (12 inches) from the end of the stem.

3. Install the actuator stem assembly into the yoke assembly (key 67). Place a support under the stem to position the lower end of the stem 254 mm (10 inches) above the bottom surface of the actuator (actuator-to-bonnet joint).

Note

When installing the lower diaphragm casing, install O-rings (key 70) into grooves found in the lower diaphragm casing before placing the casing on the yoke assembly. If the spring interferes with installation of the lower diaphragm casing, reposition the spring by rotating the adjusting nut.

4. Install the lower diaphragm casing (key 67), and secure it by tightening the four hex nuts.
5. Lubricate the seal bushing O-rings (keys 8 and 9) and the seal bushing (key 7) with lithium grease lubricant. Install the seal bushing O-rings, seal bushing (keys 8 and 9), and seal bushing retainer (key 7) and secure with four hex nuts.

NOTICE

Install the diaphragm with the fabric side facing away from the spring. Smooth the edge of the diaphragm to avoid wrinkling and be careful that the diaphragm fold does not get pinched when the diaphragm adaptor (key 245, figure 5) is installed.

NOTICE

If the diaphragm (key 3) is installed so air pressure is applied to the fabric side, it will immediately delaminate the sealing surface (smooth surface) from the fabric. The delamination can cause immediate failure of the diaphragm's ability to retain pressure.

6. Install the diaphragm backup plate, diaphragm retainer, diaphragm, O-ring, and diaphragm plate (keys 6, 5, 3, 240, and 4) on the actuator stem (key 144).
7. Carefully fold the diaphragm between the diaphragm backup plate (key 246) and the case adapter (key 245) while lowering the adapter onto the lower diaphragm casing assembly (key 67). Install all 40 cap screws (key 13) and finger tighten.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing cap screws are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 80 and 100 actuators.

NOTICE

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

Overtightening the cap screws (key 13) can damage the diaphragm. Do not exceed 68 N•m (50 lbf•ft) torque.

8. Tighten the cap screws (key 13) in the following manner. The first four cap screws tightened should be diametrically opposed and 90 degrees apart. Tighten these four cap screws to 34 N•m (25 lbf•ft).
9. Tighten the remaining cap screws in a clockwise, crisscross pattern to 34 N•m (25 lbf•ft).
10. Repeat this procedure by tightening the four cap screws, diametrically opposed and 90 degrees apart, to a torque of 68 N•m (50 lbf•ft).
11. Tighten the remaining cap screws in a clockwise, crisscross pattern to 68 N•m (50 lbf•ft).
12. After the last cap screw is tightened to 68 N•m (50 lbf•ft), all of the cap screws should be tightened again to 68 N•m (50 lbf•ft) in a circular pattern around the bolt circle.
13. Once completed, no more tightening is recommended.

NOTICE

Install the diaphragm with the fabric side facing toward the spring. Smooth the edge of the diaphragm to avoid wrinkling and be careful that the diaphragm fold does not get pinched when the upper diaphragm casing (key 1) is installed.

14. Install the diaphragm backup plate, diaphragm, diaphragm retainer, backup plate, washer (keys 246, 3, 5, 6, 37, 241 and 24), hex nut (key 241), and hex nut (key 24).
15. For actuators with a top-mounted handwheel (see figure 9), screw the actuator stem extension (key 36) as far as it will go into the actuator stem connector (key 42) before tightening the hex nut (key 28).
16. For actuators without the handwheel, Install the travel stop cap screw (key 12), and tighten the screw.
17. Position the upper diaphragm casing (key 1) on the diaphragm (key 3) and align the holes.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing cap screws are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 80 and 100 actuators.

NOTICE

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

Overtightening the cap screws (key 13) can damage the diaphragm. Do not exceed 68 N•m (50 lbf•ft) torque.

18. Insert the cap screws (key 13) into the upper diaphragm casing (key 1), and finger tighten the screws.
19. Tighten the cap screws (key 13) in the following manner. The first four cap screws tightened should be diametrically opposed and 90 degrees apart. Tighten these four cap screws to 34 N•m (25 lbf•ft).
20. Tighten the remaining cap screws in a clockwise, crisscross pattern to 34 N•m (25 lbf•ft).
21. Repeat this procedure by tightening the four cap screws, diametrically opposed and 90 degrees apart, to a torque of 68 N•m (50 lbf•ft).
22. Tighten the remaining cap screws in a clockwise, crisscross pattern to 68 N•m (50 lbf•ft).
23. After the last cap screw is tightened to 68 N•m (50 lbf•ft), all of the cap screws should be tightened again to 68 N•m (50 lbf•ft) in a circular pattern around the bolt circle.

24. Once completed, no more tightening is recommended.
25. For actuators with a top-mounted handwheel (see figure 9), mount the gear case assembly (key 41) on the actuator using cap screws (key 16). Install the hex nuts (key 47) and travel stop cap screw (if used) on the actuator stem extension (key 36). Install the gear case cover (key 53) with cap screws (key 54).
26. Mount the actuator on the valve, and secure with the actuator-to-bonnet bolting. Refer to the Installation section to connect the actuator stem to the valve plug stem.

Size 80 Side-Mounted Handwheel

The side-mounted handwheel assembly (figure 8) is normally used as a manual operator. The handwheel can be mounted in either of two position orientations so that, regardless of valve plug action, counterclockwise rotation always opens the valve. The assembly is a continuously connected type with an indicator to show neutral position. By rotating the handwheel away from neutral, the handwheel can be used to limit travel in either direction, but not both directions at the same time.

A grease fitting is provided on the gear box for periodic gear lubrication with a general purpose grease.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Key number location are shown in figure 8.

Disassembly

1. Complete steps 1 through 16 of the Disassembly portion of the Size 80 Actuator Maintenance section.
2. Unscrew the cap screws (key 88), and remove the spring case (key 85). Unscrew the cap screws (key 136), and remove the retaining flange (key 134). Do not lose the key (key 122).
3. Unscrew two screws (key 79), and remove the travel stop indicator (key 126).
4. Turn the handwheel (key 58) to raise the lower sleeve. Continue turning the handwheel until the lower sleeve is free of the worm gear (key 44). Lift out the lower sleeve, bearing and gear retainer, thrust bearing, and worm gear (keys 123, 45, 43, and 44).
5. The worm shaft (key 51) and associated parts can be removed in order to replace or lubricate them. First, remove the handwheel cap (key 127) and the handwheel (key 58). Do not lose the small ball or spring (keys 141 and 142).
6. Loosen the two set screws and unscrew the two worm retainers (keys 48 and 49). The ball bearings (key 50) will come out with the retainers. Remove the worm shaft (key 51).

Assembly

1. Pack the ball bearings (key 50) with lithium grease lubricant (key 237), and insert one ball bearing in the back worm retainer (key 48).
2. Thread the back worm retainer and ball bearing (keys 48 and 50) into the gear case. Align the set screw slot in the worm retainer with the set screw hole in the gear case, insert the set screw, and tighten.
3. Coat the worm shaft (key 51) threads with lithium grease lubricant, and slide the shaft into the gear case (key 41) so that the end of the shaft fits snugly in the back worm retainer.
4. Insert the bearing in the front worm retainer (key 49), and thread the retainer and ball bearing into the gear case. Align the set screw slot in the retainer with the set screw hole in the gear case, insert the set screw, and tighten.
5. Put the spring and ball (keys 142 and 141) in the handwheel (key 58). Slide the handwheel onto the worm shaft (key 51). Thread the handwheel cap (key 127) onto the worm shaft.
6. Pack the two thrust bearings (key 43) with lithium grease lubricant. Install one thrust bearing; then install the worm gear (key 44), followed by the second thrust bearing and the bearing and gear retainer (key 45).

7. The lower sleeve (key 123) has two screw holes in one end. Coat the sleeve threads with lithium grease lubricant, slide the end of the lower sleeve with the holes into the thrust bearing (key 43), turn the handwheel, and feed the sleeve through the worm gear. Continue turning the handwheel until the lower sleeve protrudes from the gear case. Fasten the travel stop indicator (key 126) to the sleeve with two machine screws (key 79).
8. Install the key (key 122) on the retaining flange (key 134).
9. Install the retaining flange (key 134) so that the key engages the slot in the lower sleeve. Secure the retaining flange with the cap screws (key 136).
10. Adjust the set screws (key 121) to eliminate free play in the bearings.

Note

Overtightening the set screws will make handwheel operation difficult.

11. Coat the spring adjustor (key 74) threads with lithium grease lubricant and install it over the lower sleeve.
12. Pack the thrust bearing (key 86) with lithium grease lubricant, and install it on the spring adjustor (key 74) as shown in figure 8.
13. Slide the spring case (key 85) into position, and secure with cap screws (key 88).
14. Complete steps 3 through 16 of the Assembly procedure in the Size 80 Actuator Maintenance section.

Size 80 Hydraulic Snubber

The size 80 667 actuator is available with a hydraulic snubber, as shown in figure 8, to aid vertical stability of the actuator stem movement. The snubber is adjusted by rotating the adjusting screws (key 104, figure 8) counterclockwise out of the reservoir (key 99, figure 8) to increase damping action and clockwise to decrease damping action. The adjusting screw on the right (the top one of the two adjusting screws in section B-B of figure 8) regulates downward damping action, and the screw on the left regulates upward damping action.

Size 100 Top-Mounted Handwheel (Adjustable Down Travel Stop)

Key numbers are shown in figure 9.

A top-mounted handwheel assembly is normally used as an adjustable-down travel stop to limit full extension of the actuator stem. Counterclockwise rotation will compress the spring and move the actuator stem upward. Clockwise rotation of the handwheel (key 58) allows spring action to return the actuator stem (key 144) downward.

Instructions are given below for complete disassembly and assembly. Disassemble only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Disassembly

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. Bypass the control valve. Reduce the loading pressure to atmospheric (refer to the Maintenance section), and remove the tubing or piping from the diaphragm casing.
3. Unscrew the cap screws (key 54), and remove the gear case cover (key 53).
4. Loosen the set screws (key 52) in the front and back worm retainers (keys 48 and 49) and the handwheel (key 58).

5. Remove the retaining ring (key 60), and remove the handwheel.
6. Remove front and back worm retainers (keys 48 and 49) and the bearings (key 50).
7. Remove the worm shaft (key 51).
8. Remove the power screw assembly (key 46) by placing a wrench on the double hex nuts (key 47) and unscrew the assembly from the actuator stem extension (key 36). The bearing and gear retainer, thrust bearing, and worm gear (keys 45, 43, and 44) will come out with the power screw.

Assembly

1. The front and back worm retainers (keys 48 and 49) each have a slot in their threads for a set screw (key 52). Pack the ball bearings (key 50) with lithium grease, and insert one ball bearing into the back worm retainer (key 48).
2. Thread the back worm retainer and ball bearing into the gear case. Align the slot in the worm retainer with the set screw hole in the gear case, insert the set screw (key 52), and tighten.
3. Coat the worm shaft (key 51) threads with lithium grease lubricant, and slide the shaft into the gear case so that the end of the shaft fits snugly in the back worm retainer.
4. Insert the bearing into the front worm retainer (key 49), and thread the retainer and ball bearing into the gear case. Align the slot in the retainer with the hole in the gear case, insert the set screw (key 52), and tighten.
5. Slide the handwheel onto the worm shaft (key 51), and install the retaining ring (key 60).
6. Pack the two thrust bearings (key 43) with lithium grease lubricant. Install one thrust bearing, then the worm gear (key 44), followed by the second thrust bearing and the bearing and gear retainer (key 45).
7. Coat the power screw threads (key 46) with lithium grease lubricant. Slide the power screw into the thrust bearing (key 43), turn the handwheel, and feed the sleeve through the worm gear.
8. Install the gear case cover (key 53), and tighten the cap screws (key 54).
9. Adjust the set screws (key 55) to eliminate free play in the bearings.

Note

Overtightening the set screws (key 55) will make handwheel operation difficult.

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always refer to this number when corresponding with your [Emerson sales office](#) regarding replacement parts or technical information.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

Scope of Manual

This manual provides installation, maintenance, and parts list information for the Fisher 667NS actuator. Refer to separate instruction manuals for information regarding the control valve and accessories.

Do not install, operate, or maintain 667NS actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

The 667NS actuator is a reverse-acting, spring-opposed diaphragm actuator that is used for operation of automatic control valves. The 667NS actuator yoke construction and special bonnet-to-yoke bolting provides a high structural resonant frequency that exceeds most nuclear service seismic requirements.

Specifications

Tables 1 and 2 provide specifications for the various sizes of 667NS actuators discussed in this instruction manual.

⚠ WARNING

To avoid personal injury or property damage, do not exceed pressure and temperature limits specified in table 1.

 E-mail: education@emerson.com
emerson.com/mytraining

Maximum Pressure Limitations

The casing and diaphragm of 667 actuators are pressure operated. This air pressure provides energy to compress the spring, to stroke the actuator, and lift the diaphragm away from the valve. The following explanations describe the maximum pressure limits for an actuator. Refer to table 1 for maximum values.

⚠ WARNING

To avoid personal injury or property damage, do not exceed pressure and temperature limits specified in table 1.

- **Maximum Diaphragm Pressure to Stroke the Actuator:** This is the maximum pressure that can be applied at less than full travel of the actuator. If this stroking pressure is exceeded before the upper diaphragm plate contacts the travel stop, damage to the stem or other parts might result.

- **Maximum Excess Diaphragm Pressure:** Additional pressure may be added when the actuator is at full travel. If the Maximum Excess Diaphragm Pressure is exceeded, damage to the diaphragm or diaphragm casing might result.

Because the actuator has traveled its specified travel, and the diaphragm head is physically stopped from movement, the energy from any additional air pressure is transmitted to the diaphragm and diaphragm casings. The amount of air pressure that can be added once the actuator has traveled to the stops is limited by the resultant adverse effects that may occur. Exceeding this limiting factor could result in leakage or casing fatigue due to the deformation of the upper diaphragm casing.

- **Maximum Diaphragm Casing Pressure:** If the Maximum Diaphragm Casing Pressure is exceeded, damage to the diaphragm, diaphragm casing, or actuator might result. For some actuator sizes, the maximum casing pressure is the sum of the maximum stroking pressure added to the maximum excess pressure. For other actuator sizes, the value is lower than the sum of the two pressures.

Installation

The diaphragm actuator is normally shipped mounted on a valve body. Follow the valve body instructions when installing the control valve in the pipeline.

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

If the cover (key 84, figure 4) is not in place on the actuator, install it as shown in figure 4.

⚠ WARNING

If the control valve and actuator are installed with the actuator in any position other than vertical, the actuator may not conform with safety-related qualifications. Nonvertical orientation should be part of existing qualification analysis on file at the plant site to ensure conformance with safety-related qualifications.

The control valve assembly may be installed with any orientation; however, the actuator should not be installed in ways that allow water to collect in the yoke and actuator spring areas.

Note

The 667NS actuator will not mount on a standard valve bonnet; it requires a style NS bonnet having eight bonnet-to-yoke stud bolts.

If the actuator and control valve body are separate, mount the 667NS actuator on the valve body by following the procedures in the Actuator Mounting section of this manual.

Actuator Mounting

Direct-Acting (Push-Down-to-Close) Valves

Refer to figure 1.

1. Screw the stem locknuts all the way onto the valve stem. Put the travel indicator disk, not used with the size 80 actuator, on the locknuts. The concave side of the disk should face the valve.
2. Place the actuator on the valve bonnet.
3. Insert the cap screws and tighten the hex nuts (not shown), securing the actuator to the bonnet. Tighten the cap screws to the torque shown in table 4.
4. Apply loading pressure to the actuator to retract the actuator stem fully (against the travel stop).
5. With the travel indicator scale attached to the actuator yoke, make a temporary mark on the actuator stem in line with the top mark on the scale (the mark on the end of the scale that is marked "OPEN"). (The distance from the top mark on the scale to the bottom mark is equal to the travel of the valve.)

Note

Before turning the spring adjuster on size 70 or 80 actuators, assemble the stem connector around the actuator stem and the anti-rotating lug on the yoke. Mark the actuator stem as a visual reference to verify that stem rotation does not occur. Remove the stem connector before rechecking the bench set.

6. Refer to the actuator nameplate to determine the bench set pressure range of the actuator. Reduce actuator loading pressure to the lower end of the bench set range. (For size 80, remove the cap screw (key 91, figure 4) and remove the adjusting screw cover (key 84, figure 4). Rotate the spring adjuster (key 74, figure 2 for sizes 40 and 45; key 74, figure 3 for size 70; and key 74, figure 4 for size 80) until the mark you made on the actuator stem is in line with the bottom mark on the travel indicator scale. (Replace the size 80 adjusting screw cover and cap screw when you have completed the adjustments.)
7. Increase actuator loading pressure to the upper end of the bench range and check to be sure that the mark on the actuator stem is in line with the top mark on the travel indicator scale.

If the marks are in line, the actuator is properly bench set.

If the marks are not in line, the spring is not correct for the specified bench set. It is necessary to use a different spring or a different bench set.

8. Reduce actuator loading pressure until the mark on the actuator stem is in line with the bottom mark on the travel indicator scale.

NOTICE

Do not clamp just the tip of either the valve stem or the actuator stem in the stem connector. Incomplete engagement of the valve stem and/or actuator stem in the stem connector might result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than the diameter of that stem.

9. Push the valve stem firmly against its seat, and be sure that it remains firmly against the seat. Clamp the actuator stem and valve stem between the two stem connector halves.

If necessary, increase actuator loading pressure slightly to allow the valve stem, actuator stem, and stem connector threads to match.

Insert and tighten the stem connector cap screws.

⚠ WARNING

To avoid personal injury due to the sudden, uncontrolled movement of parts, do not loosen the cap screws when the stem connector has spring or loading pressure force applied to it.

10. Raise the travel indicator disk (sizes 40 through 70 only) to the stem connector. For all sizes, thread the stem locknuts against the stem connector.
11. Remove all actuator loading pressure. Move the travel indicator scale so that the indicator disk (or pointer) is in line with the bottom mark of the travel indicator scale.
12. Check the valve travel to be sure that the valve travels fully with no overtravel.

Reverse-Acting (Push-Down-to-Open) Valves

Refer to figure 1.

1. Screw the stem locknuts all the way onto the valve stem. Put the travel indicator disk, not used with the size 80 actuator, on the locknuts. The concave side of the disk should face the valve.
2. Place the actuator on the valve bonnet.
3. Insert the cap screws and tighten the hex nuts (not shown), securing the actuator to the bonnet. Tighten the cap screws to the torque in table 4.

Note

Before turning the spring adjuster on size 70 or 80 actuators, assemble the stem connector around the actuator stem and the anti-rotating lug on the yoke. Mark the actuator stem as a visual reference to verify that stem rotation does not occur. Remove the stem connector before rechecking the bench set.

4. (For size 80, remove the cap screw (key 91, figure 4) and remove the adjusting screw cover (key 84, figure 4). Rotate the spring adjuster (key 74, figure 2 for sizes 40 and 45; key 74, figure 4 for size 70; and key 74, figure 4 for size 80) to position the actuator stem at its fully extended position.
5. With the travel indicator scale attached to the actuator yoke, make a temporary mark on the actuator stem in line with the bottom mark on the scale (the mark on the end of the scale that is marked "OPEN"). (The distance from the bottom mark on the scale to the top mark is equal to the travel of the valve.)
6. Refer to the actuator nameplate to determine the bench set pressure range of the actuator. Apply an actuator loading pressure to the actuator equal to the lower end of the bench set range and rotate the spring adjuster until the mark you made on the actuator stem is in line with the bottom mark on the travel indicator scale. (Replace the size 80 adjusting screw cover and cap screw when you have completed the adjustments.)

Figure 1. Schematic and Stem Connection Details for Fisher 667NS

7. Increase actuator loading pressure to the upper end of the bench range and check to be sure that the mark on the actuator stem is in line with the top mark on the travel indicator scale.

If the marks are in line, the actuator is properly bench set.

If the marks are not in line, the spring is not correct for the specified bench set. It is necessary to use a different spring or a different bench set.

NOTICE

Do not clamp just the tip of either the valve stem or the actuator stem in the stem connector. Incomplete engagement of the valve stem and/or actuator stem in the stem connector might result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than the diameter of that stem.

8. Pull the valve stem firmly against its seat, and be sure that it remains firmly against the seat. Clamp the actuator stem and valve stem between the two stem connector halves.

If necessary, decrease actuator loading pressure slightly to allow the valve stem, actuator stem, and stem connector threads to match.

Insert and tighten the stem connector cap screws.

⚠ WARNING

To avoid personal injury due to the sudden uncontrolled movement of parts, do not loosen the cap screws when the stem connector has spring or loading pressure force applied to it.

9. Raise the travel indicator disk to the stem connector (sizes 40 through 70 only). For all sizes, thread the stem locknuts against the stem connector.
10. Remove all actuator loading pressure. Move the travel indicator scale so that the indicator disk (or pointer) is in line with the bottom mark of the travel indicator scale.
11. Check the valve travel to be sure that the valve travels fully with no overtravel.

Loading Connection

1. Connect the loading pressure piping to the NPT internal connection in the top of the actuator yoke.
2. For size 70 actuators, remove the 1/4-inch bushing in the 1/2 NPT internal connection to increase connection size, if necessary. Use either piping or tubing.
3. Keep the length of tubing or piping as short as possible to avoid transmission lag in the control signal. If an accessory (such as a volume booster or valve positioner) is used, be sure that the accessory is properly connected to the actuator. Refer to the positioner instruction manual if necessary.
4. Cycle the actuator several times to check that the valve stem travel is correct and that the travel occurs when the correct pressure range is applied to the diaphragm.
5. If valve stem travel is incorrect, refer to the Travel procedure in the Adjustments section.
6. If the pressure range is incorrect, refer to the Spring procedure in the Adjustments section.

Adjustments

Travel

⚠ WARNING

When moving the actuator stem with diaphragm loading pressure, use caution to keep hands and tools out of the actuator stem travel path. Personal injury and/or property damage is possible if something is caught between the actuator stem and other control valve assembly parts.

Make travel adjustments when the motion observed during actuator travel is different from the travel stamped on the actuator nameplate. If the Actuator Mounting procedure was followed correctly, this adjustment should not be necessary.

When adjusting travel of a direct-acting (push-down-to-close) valve, apply a low supply pressure to the actuator diaphragm casing. This moves the valve plug off of the seat, reducing the chance of damaging the valve plug or seat during adjustments.

1. Back the stem locknuts and indicator disk away from the stem connector, and slightly loosen the stem connector cap screws.

NOTICE

Do not use wrenches or other tools directly on the valve stem. Damage to the stem surface and subsequent damage to the valve packing might result.

2. Tighten the locknuts together, use a wrench on these locknuts, and screw the valve stem either into the stem connector to lengthen travel or out of the stem connector to shorten travel.
3. Cycle the actuator to check the travel. If travel is not equal to the specified travel, adjust and check travel until correct. Tighten the stem connector cap screws when correct travel is obtained.
4. Raise the travel indicator disk by threading the stem locknuts against the stem connector.

Spring

Discussion of Bench Set

The bench set pressure range is used to adjust the initial compression of the actuator spring with the actuator assembly “on the bench”. The correct initial compression ensures that the valve-actuator assembly will function properly when it is put in service and the proper actuator diaphragm operating pressure is applied.

The bench set range is established with the assumption that there is no packing friction. When attempting to adjust the spring in the field, it is very difficult to ensure that there is no friction being applied by “loose” packing.

Accurate adjustment to the bench set range can be made during the actuator mounting process (see the Actuator Mounting Procedure) by making the adjustment before the actuator is connected to the valve.

If you are attempting to adjust the bench set range after the actuator is connected to the valve and the packing tightened, you must take friction into account. Make the spring adjustment such that full actuator travel occurs at the

bench set range (a) plus the friction force divided by the effective diaphragm area with increasing diaphragm pressure or (b) minus the friction force divided by the effective diaphragm area with decreasing diaphragm pressure.

For an assembled valve-actuator assembly, determine valve friction as described below:

1. Install a pressure gauge in the actuator loading pressure line that connects to the actuator diaphragm casing.

Note

Steps 2 and 4 require that you read and record the pressure shown on the pressure gauge.

2. Increase the actuator diaphragm pressure and read the diaphragm pressure as the actuator reaches its mid-travel position.
3. Increase the actuator diaphragm pressure until the actuator is at a travel position greater than its mid-travel position.
4. Decrease the actuator diaphragm pressure and read the diaphragm pressure as the actuator reaches its mid-travel position.

The difference between the two diaphragm pressure readings is the change in the diaphragm pressure required to overcome the friction forces in the two directions of travel.

5. Calculate the actual friction force:

$$\text{Friction Force, pounds} = 1/2 \left(\begin{matrix} \text{Difference} \\ \text{in pressure} \\ \text{readings, psig} \end{matrix} \right) \times \left(\begin{matrix} \text{Effective} \\ \text{diaphragm area,} \\ \text{inches}^2 \end{matrix} \right)$$

Refer to table 1 and 5 for the effective diaphragm area.

When determining valve friction, you can make diaphragm pressure readings at a travel position other than mid-travel if you desire. If you take readings at the zero or at the full travel position, take extra care to ensure that the readings are taken when the travel just begins or just stops at the position selected.

It is difficult to rotate the spring adjuster (key 74, figure 2, 3, or 4) when the full actuator loading pressure is applied to the actuator. Release the actuator loading pressure before adjusting. Then re-apply loading pressure to check the adjustment.

Adjustment Steps

1. Monitor actuator loading pressure carefully when making adjustments. Do not exceed the maximum pressure specifications of either the loading regulator or the actuator casings (refer to table 1 for maximum diaphragm casing pressure).
2. Each actuator spring has a fixed pressure span. Changing the spring compression shifts the span up or down to make valve travel coincide with the pressure range.

Note

Before turning the spring adjuster on size 70 or 80 actuators, assemble the stem connector around the actuator stem and the anti-rotating lug on the yoke. Mark the actuator stem as a visual reference to verify that stem rotation does not occur. Remove the stem connector before rechecking the bench set.

3. For sizes 40 through 70, turn the spring adjustor (key 74, figure 2 or 3) into the yoke to shift the span up or turn the spring adjustor out of the yoke to shift the span down. For size 80, remove the cap screw (key 91, figure 4) and remove the adjusting screw cover (key 84); then rotate the spring adjustor (key 74) to shift the span. Replace the cover and cap screw when adjustment is complete.

If the actuator has a side-mounted handwheel assembly (manual actuator), clockwise handwheel rotation closes the valve.

For successful operation, the actuator stem and valve plug stem must move freely in response to the loading pressure change on the diaphragm.

Operation

In a reverse-acting diaphragm actuator, an increasing loading pressure causes the actuator stem to move upward, compressing the spring. When the diaphragm pressure is decreased, the spring moves the actuator stem downward. This is shown graphically in figure 1. In the event of failure of the loading pressure to the diaphragm of the actuator, the actuator stem moves to the extreme downward position. Thus, by the proper selection of the valve plug action, either push-down-to-close or push-down-to-open, the control valve will either close or open on failure of the diaphragm loading pressure.

The nameplate attached to the yoke of the actuator provides information about the specific construction and operating range. The spring and diaphragm have been selected to meet the requirements of the application, and in service, the actuator should create full travel of the valve plug when the diaphragm pressure (operate) range indicated on the nameplate is applied. This diaphragm pressure range is generally 0.2 to 1.0 bar or 0.4 to 2.0 bar (3 to 15 psi or 6 to 30 psi).

Pressure in the valve body creates a force on the valve plug that has a direct effect on the actual operating diaphragm pressure range. In some instances, the valve may not stroke completely over the indicated range because the pressure conditions in the body are different from those for which the control valve has been set at the factory. A simple spring adjustment, however, may be all that is required to obtain correct travel for the diaphragm pressure range utilized. Note that the actuator spring has a fixed pressure span and that adjustment of the spring compression merely shifts this span up or down to make valve travel coincide with the diaphragm pressure range.

The nameplate specifies a bench set pressure range in addition to a diaphragm pressure (operate) range. The bench set range is that pressure range required to stroke the valve fully without any pressure in the body, as would be the case if the valve were set on the work bench. However, in service with the specified pressure drop applied across the valve, it should stroke over that diaphragm pressure (operate) range indicated on the nameplate.

When the control valve and actuator are installed, the actuator should be checked for correct travel, freedom from excessive friction, and correct action (air-to-open or air-to-close) to match the controlling instrument. For successful operation, the actuator stem and valve plug stem must move freely in response to the loading pressure change on the diaphragm.

Maintenance

Normally, only the elastomeric parts and the spring of the 667NS actuator require inspection or replacement. The maintenance instructions are divided into three subsections: Replacement of Elastomeric Parts, Disassembly, and Assembly. Perform only those steps applicable to the actuator size and required maintenance.

It is recommended that the diaphragm and all of the other elastomeric parts of the 667NS actuator be inspected every two years. The absolute maximum replacement period for any of the elastomeric parts is four years.

All maintenance operations can be performed with the valve in the line.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Replacement of Elastomeric Parts

Size 40, 45, and 70 Actuators

Perform the following if you are replacing only the elastomeric parts of the 667NS actuator, and no other maintenance is necessary. The diaphragm, the gasket, and the seal bushing O-rings are the only elastomeric parts in the size 40, 45, and 70 actuators. Key number references are shown in figure 2 for size 40 and 45 actuators and in figure 3 for size 70 actuators.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Reduce the actuator loading pressure to atmospheric pressure.
2. Remove the diaphragm casing cap screws and nuts (keys 13 and 14), and lift off the upper diaphragm casing (key 1).

NOTICE

Do not allow the valve stem to rotate during this operation since it could cause damage to the valve seats.

3. Remove the diaphragm plate cap screw and spacer (key 12 and 2). For actuator sizes 40 and 45, place a wrench on the actuator-valve stem connector assembly (key 31) to prevent the actuator stem (key 144) from rotating during the loosening of the diaphragm plate cap screw (key 12).
4. Take out the diaphragm (key 3), the upper diaphragm plate (key 4), and the lower diaphragm plate (key 71).
5. Remove the snap ring (key 72), and pull out the seal bushing (key 7). The seal bushing has two 1/4-20 UNC tapped holes provided in its top surface to be used as an aid in removing it.

6. Install three new O-rings (keys 8 and 9) on the seal bushing.
7. Lubricate the O-rings, and fill the seal bushing with lithium grease (key 99) or high-temperature, radiation-resistant, polyphenyl ether grease (key 100), as appropriate to the installation and install the bushing in the top of the actuator yoke assembly (key 73). Secure with the snap ring.
8. Coat a new gasket (key 70) with lithium grease (key 99) or high-temperature, radiation-resistant, polyphenyl ether grease (key 100), as appropriate to the installation, and place the gasket on the yoke (key 73). Assemble the lower diaphragm plate, the new diaphragm, and the upper diaphragm plate onto the actuator stem.

NOTICE

Do not allow the valve stem to rotate during this operation because it could cause damage to the valve seats.

9. Install the diaphragm plate cap screw and spacer. Tighten the cap screw to the torque value indicated in table 3. For actuator sizes 40 and 45, place a wrench on the actuator valve stem connector assembly to prevent the actuator stem from rotating during the tightening of the diaphragm plate cap screw.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 40, 45, and 70 actuators.

NOTICE

Overtightening the diaphragm casing cap screws and nuts (keys 13 and 14) can damage the diaphragm. Do not exceed a torque of 27 N•m (20 lbf•ft) when performing the following tightening procedure.

Note

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

10. Place the upper diaphragm casing into position, and replace the diaphragm casing cap screws and nuts. Tighten in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to 13 N•m (10 lbf•ft).
11. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
12. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).
13. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
14. After the last hex nut is tightened to 27 N•m (20 lbf•ft), all of the hex nuts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
15. Once completed, no more tightening is recommended.

Size 80 Actuators

The elastomeric parts in a size 80 actuator include the diaphragm and O-rings. Since replacement of these parts necessitates complete disassembly, perform the steps outlined in the procedures for disassembly and assembly of size 80 actuators.

Disassembly

Size 40, 45, and 70 Actuators

Key number references are shown in figure 2 for size 40 and 45 actuators and in figure 3 for size 70 actuators.

1. Bypass the control valve. Reduce the actuator loading pressure to atmospheric pressure, and remove the tubing or piping from the connection in the yoke cap (key 239).
2. To aid in assembly, record the position of the spring adjustor (key 74) on the actuator stem (key 144). Loosen the spring adjustor jam nut (key 102), and thread the spring adjustor jam nut and the spring adjustor off the actuator stem until all spring compression is relieved.
3. Remove the entire actuator from the valve body by removing the two cap screws from the stem connector assembly (key 31), separating the two halves of the stem connector and removing the eight bonnet stud bolt nuts.
4. Thread the spring adjustor jam nut and the spring adjustor off the actuator stem. Remove the spring seat (key 19).
5. Remove the diaphragm casing cap screws and nuts (key 13 and 14), and lift off the upper diaphragm casing (key 1).
6. Take out the diaphragm (key 3), the upper diaphragm plate (key 4), the lower diaphragm plate (key 71), and the actuator stem as an assembly. Use care when pulling the threads of the actuator stem through the seal bushing (key 7) to avoid damaging the O-rings (key 8).
7. Remove the diaphragm plate cap screw and spacer (keys 12 and 2) to separate the parts of this assembly.
8. Remove the snap ring (key 72), and lift out the seal bushing (key 7). Remove and check the O-rings (keys 8 and 9) for excessive wear or damage.
9. Remove the cap screws (key 30), and take off the lower diaphragm casing (key 64), the gasket (key 70), and the yoke cap. Lift out the spring (key 18).

Size 80 Actuators

Key number references are shown in figure 4.

1. Remove the cap screws (key 91) and the adjusting screw cover (key 84).
2. Unscrew the hex nuts (keys 85 and 86) from the actuator stem (key 93). Record the position of the spring adjustor (key 74) relative to the spring case (key 92). Loosen the spring adjustor locknut (key 90), and unscrew the spring adjustor, relieving all compression from the spring (key 18).
3. Remove the two cap screws from the stem connector assembly (key 31), and separate the stem connector halves.
4. If removal of the actuator is necessary, unbolt the eight bonnet stud bolt nuts, and remove the actuator from the valve body. Otherwise, leave the actuator mounted on the valve body.
5. Unscrew the cap screws and nuts (keys 13 and 14), and lift the upper diaphragm casing and spring case assembly (keys 1 and 92) over the spring.
6. Remove the spring seat (key 19), the bearing race and bearing (keys 88 and 89), and the guide bushing (key 97).
7. Lift off the spring.
8. Remove the actuator stem with the attached hex nuts (key 94), the diaphragm plate (key 4), the diaphragm (key 3), and the lower diaphragm plate (key 71) by carefully sliding the lower end of the actuator stem out of the seal bushing O-rings (key 8) and lifting the actuator stem with attached parts clear of the diaphragm case.
9. To aid in unfastening the actuator stem hex nuts (key 94) and to help prevent actuator stem damage, attach the stem connector assembly onto the actuator stem and grip the stem connector in a vise while unfastening the actuator stem hex nuts (key 94). Remove the hex nuts (key 94), and inspect the actuator stem and associated parts.
10. Remove the snap ring (key 72), and lift the seal bushing (key 7) and O-rings (keys 8 and 9) out of the actuator yoke (key 73).
11. Remove the O-rings.

12. Unbolt the lower diaphragm casing cap screws (key 30), and lift the lower diaphragm casing (key 64) and gasket (key 96) off the actuator yoke.

Assembly

Size 40, 45, and 70 Actuators

Key number references are shown in figure 2 for size 40 and 45 actuators and in figure 3 for size 70 actuators.

1. Place the spring (key 18) into the yoke (key 73). Coat the gasket (key 70) with lithium grease (key 99) or high-temperature, radiation-resistant, polyphenyl ether grease (key 100), as appropriate to the installation, and place the gasket on top of the yoke. Replace the yoke cap (key 239), and then place another lubricated gasket (key 70) on top of the yoke cap.
2. Attach the lower diaphragm casing (key 64) to the yoke cap with the cap screws (key 30). Tighten the cap screws to 41 N•m (30 lbf•ft) of torque for the size 40 and 45 actuators, and 102 N•m (75 lbf•ft) of torque for the size 70 actuators. Insert and evenly tighten the cap screws using a crisscross pattern.
3. Place the O-rings (keys 8 and 9) in the seal bushing (key 7).
4. Lubricate the O-rings, and fill the seal bushing with lithium grease (key 99) or high-temperature, radiation-resistant, polyphenyl ether grease (key 100) as appropriate to the installation, and reinstall the bushing in the top of the yoke. Secure with the snap ring (key 72).
5. Assemble the actuator stem (key 144), the lower diaphragm plate (key 71), the diaphragm (key 3), the upper diaphragm plate (key 4), and the diaphragm plate cap screw and spacer (keys 12 and 2). Tighten the cap screw to the torque value indicated in table 3; then place this assembly in the actuator. Take care when pushing the actuator stem through the seal bushing so that the threads do not damage the O-rings.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 40, 45, and 70 actuators.

NOTICE

Overtightening the diaphragm casing cap screws and nuts (keys 13 and 14) can damage the diaphragm. Do not exceed a torque of 27 N•m (20 lbf•ft) when performing the following tightening procedure.

Note

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

6. Install the upper diaphragm casing (key 1), and secure with the cap screws and nuts (keys 13 and 14) in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to 13 N•m (10 lbf•ft).
7. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 13 N•m (10 lbf•ft).
8. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to a torque of 27 N•m (20 lbf•ft).

9. Tighten the remaining hex nuts in a clockwise, criss-cross pattern to 27 N•m (20 lbf•ft).
10. After the last hex nut is tightened to 27 N•m (20 lbf•ft), all of the hex nuts should be tightened again to 27 N•m (20 lbf•ft) in a circular pattern around the bolt circle.
11. Once completed, no more tightening is recommended.

Table 6. Size 80 Casing Cap Screw Torque Values

DIAPHRAGM MATERIAL	INITIAL TORQUE	FINAL TORQUE
	N•m (lbf•ft)	N•m (lbf•ft)
EPDM / Meta-Aramid	41 (30)	82 ± 13 (60 ± 10)
Nitrile, Silicone, FKM/Meta-Aramid	34 (25)	68 (50)

12. Lift the spring (key 18) and spring seat (key 19) into position. Apply lithium grease to the threads of the actuator stem and to the surface of the spring adjustor (key 74) that contacts the spring seat. These locations are indicated on the assembly drawing in figures 2 and 3. Thread the spring adjustor on the actuator stem so that it matches the position recorded during disassembly. Thread the spring adjustor jam nut (key 102) up against the spring adjustor, and tighten securely.
13. Thread the stem hex nuts (keys 69 and 75) on the valve plug stem, and place the travel indicator (key 34) on these nuts with the cupped portion pointing towards the valve body.
14. Mount the actuator on the valve body, and make up the stem connection by following the procedures in the Actuator Mounting section.

Size 80 Actuators

Key number references are shown in figure 4.

1. Coat a new gasket (key 96) with lithium grease (key 99) or high-temperature, radiation-resistant, polyphenyl ether grease (key 100), as appropriate to the installation, and place the gasket on the yoke (key 73). Position the lower diaphragm casing (key 64) on the yoke. Insert and tighten the cap screws (key 30) to 102 N•m (75 lbf•ft) torque.
2. Insert new O-rings (keys 8 and 9) into the seal bushing (key 7). Lubricate the O-rings, and fill the seal bushing with lithium grease (key 99) or high-temperature, radiation-resistant, polyphenyl ether grease (key 100) or equivalent, as appropriate to the installation. Place the seal bushing and O-rings into the yoke, and install the snap ring (key 72).
3. To aid in assembling the actuator stem (key 93) and associated parts (keys 94, 4, 3, and 71), attach the stem connector assembly (key 31) onto the actuator stem, and grip the stem connector in a vise.
4. Slide the lower diaphragm plate (key 71), the diaphragm (key 3), and the upper diaphragm plate (key 4) onto the actuator stem. Slide the first hex nut (key 94) onto the stem, tighten the hex nut to 542 N•m (400 lbf•ft), slide the second hex nut onto the stem, and tighten it securely against the first hex nut. Remove the subassembly from the vise, and remove the stem connector assembly (key 31) from this subassembly.
5. Slide the shorter end of the actuator stem through the seal bushing and the O-rings (key 8), and align the diaphragm cap screw holes with the lower diaphragm case cap screw holes.
6. Lubricate the guide bushing (key 97) with lithium grease or high-temperature, radiation-resistant, polyphenyl ether grease, as appropriate to the installation. Lubricate the bearing race and bearing (keys 88 and 89) with lithium grease.
7. Position the spring (key 18), the spring seat (key 19), the lubricated guide bushing (key 97), and the lubricated bearing race and bearing on top of the diaphragm plate as shown in figure 4.
8. If the spring case assembly (key 92) has been removed from the upper diaphragm casing, replace it, making sure the vent holes in the diaphragm casing and in the spring case are aligned, and tighten the cap screws (key 30) to 102 N•m (75 lbf•ft) torque. Lower the diaphragm casing and spring case assembly onto the diaphragm.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following tightening sequence with a manual torque wrench for size 80 actuators.

NOTICE

Overtightening the diaphragm casing cap screws and nuts can damage the diaphragm. Do not exceed the following maximum torque values for the appropriate diaphragm material: EPDM/Meta-Aramid: 95 N•m (70 lbf•ft); Nitrile, Silicone, FKM (fluorocarbon) / Meta-Aramid: 68 N•m (50 lbf•ft).

Note

Do not use lubricant on these cap screws and nuts. Fasteners must be clean and dry.

9. Insert the diaphragm casing cap screws and nuts (keys 13 and 14) and tighten in the following manner. The first four hex nuts tightened should be diametrically opposed and 90 degrees apart. Tighten these four hex nuts to the initial torque value found in table 6 for the diaphragm material being used.
10. Tighten the remaining hex nuts in a clockwise, crisscross pattern to the initial torque value found in table 6 for the diaphragm material being used.
11. Repeat this procedure by tightening four hex nuts, diametrically opposed and 90 degrees apart, to the final torque value that is specified in table 6 for the diaphragm material being used.
12. Tighten the remaining hex nuts in a clockwise, crisscross pattern to the final torque value that is specified in table 6 for the diaphragm material being used.
13. After the last hex nut is tightened, complete another tightening sequence. Tighten in a circular pattern around the bolt circle to the final torque value that is specified in table 6 for the diaphragm material being used.
14. Once completed, no more tightening is recommended.
15. Lubricate the spring adjustor (key 74) threads and the bearing race and bearing with lithium grease. Thread the spring adjustor (key 74) into the spring case assembly so that the spring adjustor matches the position recorded in step 2 of the disassembly procedures for size 80 actuators. Also, make sure that the spring adjustor properly engages the spring seat.
16. Turn the spring adjustor hex nut (key 90) tightly against the spring case.
17. Lubricate the bearing race and bearing with lithium grease, and slide them over the actuator stem into the spring adjustor. Insert the bearing retainer snap ring (key 87) into the spring adjustor. Thread the two hex nuts (keys 85 and 86) onto the actuator stem. If the hex nuts (keys 85 and 86) are not used as a travel stop, thread them onto the actuator stem until they touch the spring adjustor. Back them off approximately 3.2 mm (1/8-inch), and lock them together. If these hex nuts (keys 85 and 86) are used as a travel stop, thread them onto the actuator stem so that they do not restrict actuator travel during travel adjustment. Adjust the hex nuts as outlined in the Actuator Mounting section.
18. Screw the two hex nuts (key 69) onto the valve plug stem. Mount the actuator on the valve body, and make the stem connection by following the procedures in the Actuator Mounting section.

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always refer to this serial number when corresponding with your [Emerson sales office](#) regarding replacement parts or technical information.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts List

Introduction

Scope of Manual

This instruction manual provides information on the installation, maintenance, and parts ordering for Fisher 685 piston actuators. Refer to separate instruction manuals for information regarding other equipment and accessories used with these actuators.

Do not install, operate, or maintain a Fisher 685 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

The Fisher 685 is a double acting piston actuator that provides accurate, high thrust output for short to long travel applications. This actuator is designed for use with a variety of medium to large Fisher sliding-stem control valves including the easy-e™, FB, TBX, HP, EH, and 461.

Table 1. Specifications

Operating Pressure⁽¹⁾

Minimum: 2.7 bar (40psig)

Maximum Allowable: 10.3 bar (150 psig)

Consult your [Emerson sales office](#) for supply pressures under 2.7 bar (40 psi)

Travel⁽²⁾

25 mm (1 inch) through 610 mm (24 inch)

See table 2

Thrust Capabilities

See table 3

Piston Diameter and Area⁽²⁾

Available in 51 mm (2 inch) increments between 305 mm (12 inch) and 660 mm (26 inch)

See table 2

Operative Temperature Limits

Standard: -40 to 93°C (-40 to 200°F)

Low Temperature: -54 to 93°C (-65 to 200°F)⁽³⁾

High Temperature: -29 to 204°C (-20 to 400°F)⁽³⁾

Yoke Boss and Valve Stem Diameter

■ 127 mm (5H inch) yoke boss with 32 mm (1-1/4 inch) stem ■ 178 mm (7 inch) yoke boss with 51 mm (2 inch) stem

Pressure Connections

Standard: 3/4 NPT

Optional: 1 and 1-1/4 NPT

Instrument Mounting

Mounting kits are available for use with the FIELDVUE DVC6200 Series positioner

Construction Materials

PART	MATERIAL
Yoke	ASTM A36 (steel)
Piston	ASTM A36 (steel)
Cylinder	305 to 559 mm (12 to 22 inch) Cylinder: 1026 DOM (steel) with chrome-plated bore 610 to 660 mm (24 to 26 inch) Cylinder: ASTM A516 Grade 70 (steel) with fluoropolymer coated bore
Upper/Lower Heads	ASTM A36 (steel)
Tie Bolt	ASTM A311 1045, Class B (steel)
Piston Rod	S31603 (316L stainless steel)
Stem Connector	ASTM A36 (steel)

Weights

Optional Certifications⁽⁴⁾

- Pressure Equipment Directive (PED) 2014/68/EU
- Complies with the requirements of ATEX Group II Category 2 Gas and Dust

- Customs Union Technical Regulations (CU TR) 010/2011 and 012/2011

Fisher 685 actuators have been evaluated for ignition hazard and certified for CUTR 012/2011 under “protection by constructional safety”. To ensure conformity with CUTR, only Fisher parts and materials can be used.

1. The pressure/temperature limits in this bulletin and any other applicable standard or code should not be exceeded.
2. Consult factory for larger travels or cylinder diameters. The Fisher 585C family of actuators are available for smaller travels or cylinder diameters.
3. Consult factory for applications requiring low or high temperature requirements.
4. Refer to the product nameplates to determine which certifications each actuator construction possesses.

Specifications

Specifications for 685 piston actuators are given in table 1. Refer to the nameplate affixed to the actuator yoke for specifications specific to individual constructions.

Principle of Operation

685 piston actuators utilize a pneumatically controlled piston that moves inside of a cylinder to generate thrust. A seal contained on the circumference of the piston provides a seal between the piston and the cylinder, preventing supply pressure leakage.

From an equilibrium state, the actuator operates by reacting to a force unbalance that is created by increasing supply pressure on one side of the piston, and decreasing it on the other. This moves the piston up or down, and results in a repositioning of the attached control valve. Travel can be adjusted using travel limits within a valve positioner, which limit the travel range of the actuator. The optional handwheel manual override does not have the ability to act as a hard travel stop.

An optional handwheel manual override is capable of extending or retracting the actuator manually and can be engaged at any position from full open to full close. This override utilizes a worm gear assembly that is attached to the stem connector and not attached to the cylinder or piston rod. This enables the manual override to reposition the control valve even if the actuator cylinder or piston is removed for maintenance.

26		2	6350	14000

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

To avoid personal injury or property damage caused by bursting of pressure-retaining parts, be certain the actuator cylinder pressure does not exceed the limits listed in table 1. Use pressure-limiting or pressure-relieving devices to prevent cylinder pressure from exceeding these limits.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

Dropping the actuator and any attached accessories and/or valve may cause personal injury and/or equipment damage. For all mounting procedures use an adequately sized chain, sling, hoist, or crane to handle the actuator and any attached accessories and/or valve. Use caution during lifting and handling to prevent slippage, swinging, faulty equipment connections, or sudden shock loads.

NOTICE

Special care must be taken when installing an actuator in a horizontal service orientation. To avoid cantilever loads on the valve stem and yoke, it is the customer's responsibility to ensure proper support for a horizontal actuator.

When an actuator and control valve are shipped together as a control valve assembly, the actuator is normally mounted on the valve. Follow the valve instructions when installing the valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the actuator mounting procedures in this instruction manual. Refer to the individual product instruction manuals for the installation or mounting of a FIELDVUE DVC6200 digital valve controller or 3610 positioner.

If the actuator is being installed without a positioner, the cylinder loading pressures should be supplied through a 4-way solenoid valve or a switching valve. The top and bottom sides of the piston are pressurized through the upper and lower heads (i.e. top and bottom of the cylinder).

The supply pressure medium should be clean, dry filtered air. If the supply source is capable of exceeding the maximum actuator operating pressure or positioner supply pressure, appropriate steps must be taken during installation to protect the positioner and all connected equipment against over pressurization.

The control valve should be located where it will be accessible for servicing. Room should be left above and below the control valve to permit removal of the actuator and valve plug.

Three-Way Valve Applications Note

In three-way valve applications where the actuator fully strokes at a frequency of once per minute or faster, and the stroking speed is rapid (less than 0.5 seconds per stroke), there is a possibility that the stem can fracture at the plug if the actuator cylinder pressure is greater than 5.5 bar (80 psig). This can cause loss of control of process fluid and further damage to the actuator. Consideration should be given to the use of high-strength, fatigue-resistant stem materials in these applications.

⚠ WARNING

To avoid loss of control of process fluid and subsequent personal injury or property damage caused by bursting of pressure-retaining parts, be sure the cylinder pressure does not exceed 5.5 bar (80 psig) in high cycle-rate, fast stroking speed, three-way valve applications.

Actuator Mounting

The following procedure describes how to mount a 685 actuator on a push-down-to-close valve so that the piston rod to valve plug stem connection allows full travel and proper shutoff. Key numbers referenced in the following steps are shown in figures 3 and 4.

If you purchase a 685 actuator for field installation on a control valve, mount the actuator on the valve and secure it to the bonnet with the eight bonnet-to-actuator bolts. The stem connection should then be made up to clamp the actuator stem and valve plug stem together to provide proper valve travel.

NOTICE

If the valve stem is allowed to remain in the up position (towards the actuator) during mounting, it can interfere with the actuator mounting, possibly damage valve stem threads, or bend the valve stem. Be sure the valve stem is pushed down (into the valve body), away from the actuator while mounting.

To avoid damaging the seating surfaces, do not rotate the valve plug while it is seated. Also avoid damage to the valve plug stem by careful use of tools during travel adjustment.

1. Thread two lifting eyes into the free ports on the upper head (key 1) 180 degrees apart. Reference tables 4 and 5 for approximate weights of the actuator to select an appropriate lifting eye. Attach appropriate rigging gear to the lifting eyes.
2. Slowly lower the actuator down onto the valve. Once the actuator is in place, insert the bonnet-to-actuator bolts and tighten the hex nuts.

3. Turn the two stem locknuts (if present) all the way onto the valve stem thread.
4. Starting with the cylinder fully retracted, manually, or with air pressure, extend the piston rod to the specified valve travel.
5. Attach the stem connector (key 18), clamping the piston rod (key 17) to the valve stem. Be sure you also attach the feedback arm and travel indicator.
6. Cycle the actuator to check availability of desired total travel and that the valve plug seats before the cylinder reaches the end of its stroke. You can make minor travel adjustments, if necessary, by loosening the stem connector slightly, tightening the locknuts together, and (with the valve plug off the seat) screwing the stem either into or out of the stem connector by means of a wrench on the locknuts.
7. If the total travel is adequate, tighten the stem connector (key 18) securely, lock the stem locknuts (if present) against the connector, and adjust the indicator scale (key 22) on the yoke (key 21) to show valve plug position.
8. Provide a gauge, if necessary, to measure the pressure to the actuator. Make a final adjustment on the positioner to set the starting point of valve travel and to obtain full travel for the given instrument range.

Handwheel Operation

If manual operation is required, the actuator should be equipped with a manual handwheel.

NOTICE

To avoid damage to actuator parts and difficult operation of actuator handwheels, open the bypass valve (key 66) before using a handwheel.

The bypass assembly is furnished only when a handwheel actuator is specified. The bypass allows the pressure to equalize on either side of the piston, so that the manual actuator can be used to position the control valve. Flow through the bypass tubing is controlled by an angle needle valve, which is operated manually. This valve should be closed when air pressure is being used to operate the actuator.

Key numbers referenced in the following steps are shown in figures 2 and 3. Refer to table 7 for handwheel specifications.

1. Open the bypass valve.
2. Rotate the handwheel (key 45) to position the override engage pin (key 38) with the hole in the stem connector (key 18). Use the engage pin control knob (key 33) to insert the override engage pin into the stem connector until it stops. Refer to figure 2 for engage pin control knob operation.

Note

Depending on construction, the handwheel may have operation information stamped into the part. Always refer to steps 3 and 4 for operation information specific to push-down-to-close and push-down-to-open valves.

3. For a push-down-to-close valve: Rotate the handwheel (key 45) clockwise to close the valve and counterclockwise to open the valve.
4. For a push-down-to-open valve: Rotate the handwheel (key 45) counterclockwise to close the valve and clockwise to open the valve.
5. To disengage the manual handwheel, rotate the handwheel (key 45) to relieve any load placed on the override engage pin (key 38), and use the engage pin control knob (key 33) to remove the override engage pin from the stem connector (key 18). Refer to figure 2 for engage pin control knob operation.

Table 7. Handwheel Specifications

ACTUATOR SIZE	OUTPUT THRUST		HANDWHEEL DIAMETER		TURNS PER mm OF TRAVEL	TURNS PER INCH OF TRAVEL	MAXIMUM RIM FORCE REQUIRED	
	N	lbs	mm	Inch			N	lbs

14 to 18	88964	20000	406	16	3.0	80	380	85
20 to 26	133447	30000	610	24	2.8	72	450	100

Figure 2. Engage Pin Control Knob Operation

Maintenance

⚠ WARNING

Avoid personal injury from sudden release of process pressure. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Instructions are given below for complete disassembly of the actuator, seal replacement, and O-ring replacement. When inspection or repair is necessary, disassemble the actuator only as far as is required to accomplish the job. Key numbers referenced in the following steps are shown in figures 3 and 4.

Actuator Removal

The following procedure is for the removal of the actuator from a valve.

1. Disconnect the actuator tubing from the pressure connections on the upper and lower heads (keys 1 and 9) and positioner.

Note

Refer to the appropriate instruction manual for any maintenance or adjustments that need to be made on the positioner.

2. Break the stem connection by removing hex nuts (key 57), studs (key 58), and lock washers (key 10) from the stem connector (key 18).
3. Remove the bonnet-to-actuator bolting securing the actuator to the valve bonnet.
4. Thread two lifting eyes into the free ports on the upper head (key 1) 180 degrees apart. Reference tables 4 and 5 for approximate weights of the actuator to select an appropriate lifting eye. Attach appropriate rigging gear to both lifting eyes and lift the actuator away from the valve bonnet and stem.
5. Place the actuator upside-down with the upper head (key 1) flat against the ground. Cloth or wood should be used to prevent against paint damage.
6. Refer to the Actuator Mounting section of this manual for instructions on mounting and installing the actuator onto a valve

Seal and O-ring Replacement

The following procedure is for the replacement of the internal piston seals, bearing seals, and O-rings.

1. Complete Actuator Removal procedures above.
2. Loosen tie bolt hex nuts (key 11) in a crisscross pattern. Remove tie rod hex nuts and lock washers (key 10).
3. Remove the yoke (key 21) and the lower head (key 9) assembly from the cylinder (key 4) and place onto a flat surface with the O-ring side facing up. Using straps, secure this assembly to a solid structure to prevent it from falling over.
4. Extract bearing assembly (keys 12, 13, 14, and 15) from lower head (key 9) by removing the bearing retaining ring (key 16).
5. Remove the piston wiper seal (key 15), O-ring (key 13), and quad seal (key 12) from the bearing (key 14).
6. Clean bearing (key 14) with a light degreaser, if needed.
7. Lightly grease the new O-ring (key 13) and quad seal (key 12), then install onto bearing (key 14). Without grease, install a new piston wiper seal (key 15) onto the bearing.
8. Reinstall bearing assembly (keys 12, 13, 14, and 15) into lower head (key 9) and secure in place with the bearing retaining ring (key 16).
9. Remove the O-ring (key 2) from the lower head (key 9) and clean the groove with a light degreaser.
10. Lightly grease the new O-ring (key 2) and install on lower head (key 9).
11. Remove tie bolts (key 3) from upper head (key 1).
12. Lift piston assembly (keys 5, 6, 7, 17, and 19) out from cylinder (key 4) and place on a flat surface.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

685 Piston Actuator

June 2023

Instruction Manual

D103626X012

13. Remove the wear ring (key 6) and quad seal (key 7) from the piston (key 5).
14. Thread locking compound is applied to the threads of the piston rod (key 17) by the manufacturer during initial assembly. As a result, disassembly will require heating to loosen the thread locking compound. To remove the piston rod O-ring (key 19), heat the piston assembly using a torch and unthread the piston rod (key 17) from the piston (key 5).
15. After the piston rod (key 17) has completely cooled, remove the piston rod O-ring (key 19). Clean the piston rod O-ring groove with a light degreaser. Lightly grease a new piston rod O-ring and install onto the piston rod.
16. Reinstall piston rod (key 17) onto piston (key 5) using thread locking compound.
17. Clean piston seal grooves. Install new lightly greased quad seal (key 7) onto piston (key 5).
18. Without grease, trim to length and then install a new wear ring (key 6).
19. Lift cylinder (key 4) vertically and place on a flat surface. Take extra precaution to avoid scratching or gouging the inner diameter of the cylinder.
20. Remove O-ring (key 2) from the upper head (key 1) and clean the seal groove. Install lightly greased new O-ring into upper head seal groove.
21. Install cylinder (key 4) onto upper head (key 1) making sure the O-ring (key 2) does not move out of its groove.
22. Carefully install the piston assembly (keys 5, 6, 7, 17, and 19) into cylinder (key 4) making sure all seals and O-rings stay in place on the outside diameter of the piston (key 5).
23. Install tie bolts (key 3) into upper head (key 1).
24. Carefully install the yoke (key 21) and the lower head (key 9) assembly onto cylinder (key 4) taking care not to damage threads on the tie bolts (key 3). Be sure the O-ring (key 2) is in place during this step.
25. Install lock washers (key 10) and tie rod hex nuts (key 11) onto tie bolts (key 4). Torque in a crisscross pattern according to table 8.
26. Refer to the Actuator Mounting section of this manual for instructions on mounting and installing the actuator onto a valve.

Table 8. Tie Bolt Torque

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, refer to the serial numbers (there are two serial numbers located on the actuator) found on the actuator nameplate (key 22).

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts Kits

Includes all soft seals and O-rings required for seal and O-ring replacement in standard operating temperature constructions. Refer to figures 3 and 4.

Introduction

Scope of Manual

This instruction manual provides information on the installation, maintenance, and parts ordering for Fisher 685SE and 685SR piston actuators. Refer to separate instruction manuals for information regarding other equipment and accessories used with these actuators.

Do not install, operate, or maintain 685SE or 685SR actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. **To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings.** If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

The 685SE and 685SR are medium to large spring-return double-acting piston actuators that provide accurate, high thrust output for short to long travel applications. These actuators are designed for use with a variety of medium to large Fisher sliding-stem control valves including the easy-e™, FB, TBX, CVX, HP, EH, and 461.

These actuators feature an internal bias spring that forces the actuator piston rod to extend (685SE) or retract (685SR) upon a loss of supply pressure, thereby ensuring a fail-closed or fail-open mode of operation. This effectively eliminates the need for a trip valve and volume tank in most constructions.

Table 1. Specifications

Operating Pressure⁽¹⁾

Minimum: 2.7 bar (40psig)

Maximum Allowable: 10.3 bar (150 psig)

Consult your [Emerson sales office](#) for supply pressures under 2.7 bar (40 psi)

Travel⁽²⁾

25 mm (1 inch) through 610 mm (24 inch).

Optional Certifications⁽⁵⁾

- Pressure Equipment Directive (PED) 2014/68/EU
- Complies with the requirements of ATEX Group II Category 2 Gas and Dust

- Customs Union Technical Regulations (CU TR) 010/2011 and 012/2011

Fisher 685SE and 685SR actuators have been evaluated for ignition hazard and certified for CUTR 012/2011 under “protection by constructional safety”. To ensure conformity with CUTR, only Fisher parts and materials can be used.

1. The pressure/temperature limits in this instruction manual and any other applicable standard or code should not be exceeded.

2. Contact your Emerson sales office for larger travels or cylinder diameters. The Fisher 657, 667, and 585C family of actuators can be used for smaller travels or cylinder diameters.

3. Contact your Emerson sales office for applications requiring low or high temperature requirements.

4. Contact your Emerson sales office for applications requiring a manual override on a size 28 actuator.

5. Refer to the product nameplates to determine which certifications each actuator construction possesses.

Specifications

Specifications for the 685SE and 685SR piston actuators are shown in table 1. Refer to the nameplate affixed to the actuator yoke for specifications specific to individual constructions.

Principle of Operation

685SE and 685SR piston actuators utilize a piston that moves inside of a cylinder to generate thrust. A seal contained on the circumference of the piston provides a seal between the piston and the cylinder, preventing supply pressure leakage. A bias spring that is either below or above the piston, depending on construction, will retract or extend the piston rod upon a loss of supply pressure. This fail action will result in forcing an attached control valve to either fail-open or fail-closed.

From an equilibrium state, the actuator operates by reacting to a force unbalance that is created by increasing supply pressure on one side of the piston, and decreasing it on the other. This moves the piston up or down, and results in a repositioning of the attached control valve. Travel can be adjusted using travel limits within a valve positioner, which limit the travel range of the actuator. The optional handwheel manual override does not have the ability to act as a hard travel stop.

An optional handwheel or hydraulic hand-pump manual override is capable of extending or retracting the actuator manually and can be engaged at any position from full open to full close. This handwheel override utilizes a worm gear assembly that is attached to the stem connector and not attached to the cylinder or piston rod. This enables the handwheel manual override function to reposition the control valve even if the actuator cylinder or piston is removed for maintenance. The hydraulic hand-pump override utilizes a hydraulic cylinder that is connected to the piston rod, which is controlled by a manual hand-pump.

Table 6. Lifting Point Load Ratings

ACTUATOR SIZE	LIFTING ORIENTATION	NUMBER OF LIFTING POINTS USED	MAXIMUM LOAD	
			kg	lbs
10	Actuator Centerline Horizontal	2	810	1800
12 to 24		2	1540	3400
26 to 28		2	2860	6300
10	Actuator Centerline Vertical	2	2080	4600
12 to 24		2	3760	8300
26 to 28		2	6350	14000

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

To avoid personal injury or property damage caused by bursting of pressure-retaining parts, be certain the actuator cylinder pressure does not exceed the limits listed in table 1. Use pressure-limiting or pressure-relieving devices to prevent cylinder pressure from exceeding these limits.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

Dropping the actuator and any attached accessories and/or valve may cause personal injury and/or equipment damage. For all mounting procedures use an adequately sized chain, sling, hoist, or crane to handle the actuator and any attached accessories and/or valve. Use caution during lifting and handling to prevent slippage, swinging, faulty equipment connections, or sudden shock loads.

NOTICE

Special care must be taken when installing an actuator in a horizontal service orientation. To avoid cantilever loads on the valve stem and yoke, it is the customer's responsibility to ensure proper support for a horizontal actuator.

When an actuator and control valve are shipped together as a control valve assembly, the actuator is normally mounted on the valve. Follow the valve instructions when installing the valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the actuator mounting procedures in this instruction manual. Refer to the individual product instruction manuals for the installation or mounting of a FIELDVUE DVC6200 digital valve controller or 3610 positioner.

If the actuator is being installed without a positioner, the cylinder loading pressures should be supplied through a 4-way solenoid valve or a switching valve. Pressure connection locations are indicated below:

- 685SE Actuators: Side of the outer spring cartridge and bottom of the lower head.
- 685SR Actuators: Top of the upper head and side of the outer spring cartridge.

The supply pressure medium should be clean, dry filtered air. If the supply source is capable of exceeding the maximum actuator operating pressure or positioner supply pressure, appropriate steps must be taken during installation to protect the positioner and all connected equipment against over pressurization.

The control valve should be located where it will be accessible for servicing. Room should be left above and below the control valve to permit removal of the actuator and valve plug.

Three-Way Valve Applications Note

In three-way valve applications where the actuator fully strokes at a frequency of once per minute or faster, and the stroking speed is rapid (less than 0.5 seconds per stroke), there is a possibility that the stem can fracture at the plug if the actuator cylinder pressure is greater than 5.5 bar (80 psig). This can cause loss of control of process fluid and further damage to the actuator. Consideration should be given to the use of high-strength, fatigue-resistant stem materials in these applications.

⚠ WARNING

To avoid loss of control of process fluid and subsequent personal injury or property damage caused by bursting of pressure-retaining parts, be sure the cylinder pressure does not exceed 5.5 bar (80 psig) in high cycle-rate, fast stroking speed, three-way valve applications.

Actuator Mounting

The following procedure describes how to mount a 685SE or 685SR actuator on a push-down-to-close valve so that the piston rod to valve plug stem connection allows full travel and proper shutoff. Key numbers referenced in the following steps are shown in figures 3, 4, 5, and 6.

NOTICE

The 685SE actuator spring load will force the piston rod to extend out of the cylinder, and it can come into contact with the valve stem during actuator mounting.

If the valve stem is allowed to remain in the up position (towards the actuator) during mounting, it can interfere with the actuator mounting, possibly damage valve stem threads or bend the valve stem. Be sure the valve stem is pushed down (into the valve body), away from the actuator while mounting.

To avoid damaging the valve plug seating surfaces, do not rotate the valve plug while it is seated. Also avoid damage to the valve plug stem by careful use of tools during travel adjustment.

For 685SE actuators only: It may be necessary to apply a temporary loading pressure to the bottom cylinder pressure connection to move the piston rod away from the valve stem during installation. If it is not possible to provide a temporary loading pressure, exercise caution when lowering the actuator over the valve stem to prevent damage to the valve stem or piston rod.

⚠ WARNING

When moving the piston rod with loading pressure applied, exercise caution to keep hands and tools out of the piston rod travel path. If the loading pressure is accidentally disconnected, personal injury and property damage is possible if something is caught between the piston rod and other control valve parts.

1. For 685SE Actuators: Using the lifting points along the outside perimeter of the outer spring cartridge (key 23) attach appropriate rigging gear to both lifting points.
For 685SR Actuators: Thread two lifting eyes into the free ports on the upper head (key 1) 180 degrees apart. Reference tables 4 and 5 for approximate weights of the actuator to select an appropriate lifting eye. Attach appropriate rigging gear to the lifting eyes.
2. Lower the actuator onto the valve bonnet.
 - a. For the 90.5 mm (3-9/16 inch) yoke boss: Slowly lower the actuator down onto the valve. As the yoke passes over the end of the valve stem, place the yoke locknut over the valve stem. Once the actuator is in place, screw the yoke locknut onto the valve bonnet and tighten.
 - b. For all other yoke bosses: Slowly lower the actuator down onto the valve. Once the actuator is in place, insert the bonnet-to-actuator bolts and tighten the hex nuts.
3. Turn the two stem locknuts (if present) all the way onto the valve stem thread.

4. Starting with the piston rod fully retracted, manually, or with air pressure, extend the piston rod to the specified valve travel.
5. Attach the stem connector (key 18), clamping the piston rod (key 17) to the valve stem. Be sure to also attach the feedback arm and travel indicator.
6. Cycle the actuator to check availability of desired total travel and that the valve plug seats before the cylinder reaches the end of its stroke. You can make minor travel adjustments, if necessary, by loosening the stem connector slightly, tightening the locknuts together, and (with the valve plug off the seat) screwing the stem connector either into or out of the stem connector by means of a wrench on the locknuts.
7. If the total travel is adequate, tighten the stem connector (key 18) securely, lock the stem locknuts (if present) against the connector, and adjust the indicator scale (key 22) on the yoke (key 21) to show valve plug position.
8. Provide a gauge, if necessary, to measure the pressure to the actuator. Make a final adjustment on the positioner to set the starting point of valve travel and to obtain full travel for the given instrument range.

Handwheel Operation

If manual operation is required, the actuator should be equipped with a manual handwheel for sizes 10 to 26.

NOTICE

To avoid damage to actuator parts and difficult operation of actuator handwheels, open the bypass valve (key 66) before using a handwheel.

The bypass assembly is furnished only when a handwheel actuator is specified. The bypass allows the pressure to equalize on either side of the piston, so that the manual actuator can be used to position the control valve. Flow through the bypass tubing is controlled by an angle needle valve, which is operated manually. This valve should be closed when air pressure is being used to operate the actuator.

Key numbers referenced in the following steps are shown in figures 2, 5, and 6. Refer to table 7 for handwheel specifications.

1. Open the bypass valve.
2. Rotate the handwheel (key 45) to position the override engage pin (key 38) with the hole in the stem connector (key 18). Use the engage pin control knob (key 33) to insert the override engage pin into the stem connector until it stops. Refer to figure 2 for engage pin control knob operation.

Note

Depending on construction, the handwheel may have operation information stamped into the part. Always refer to steps 3 and 4 for operation information specific to push-down-to-close and push-down-to-open valves.

3. **For a push-down-to-close valve:** Rotate the handwheel (key 45) clockwise to close the valve and counterclockwise to open the valve.
4. **For a push-down-to-open valve:** Rotate the handwheel (key 45) counterclockwise to close the valve and clockwise to open the valve.
5. To disengage the manual handwheel, rotate the handwheel (key 45) to relieve any load placed on the override engage pin (key 38), and use the engage pin control knob (key 33) to remove the override engage pin from the stem connector (key 18). Refer to figure 2 for engage pin control knob operation.

Figure 2. Engage Pin Control Knob Operation

528909

Table 7. Handwheel Specifications

ACTUATOR SIZE	OUTPUT THRUST		HANDWHEEL DIAMETER		TURNS PER mm OF TRAVEL	TURNS PER INCH OF TRAVEL	MAXIMUM RIM FORCE REQUIRED	
	N	lbs	mm	Inch			N	lbs
10 to 12	44482	10000	305	12	3.8	96	290	65
14 to 18	88964	20000	406	16	3.0	80	380	85
20 to 26	133447	30000	610	24	2.8	72	450	100

Maintenance

⚠ WARNING

Avoid personal injury from sudden release of process pressure. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

⚠ WARNING

The outer and inner spring cartridge (keys 23 and 57) contains a spring under compression. Do NOT attempt to dismantle any part of the spring cartridge without first consulting your local [Emerson sales office](#) to avoid personal injury.

Instructions are given below for complete disassembly of the actuator, seal replacement, and O-ring replacement. When inspection or repair is necessary, disassemble the actuator only as far as is required to accomplish the job. Key numbers referenced in the following steps are shown in figures 3, 4, 5, and 6.

Actuator Removal

The following procedure is for the removal of the actuator from a valve.

For 685SE actuators only: It may be necessary to apply a temporary loading pressure to the bottom cylinder pressure connection to move the piston rod away from the valve stem during removal. If it is not possible to provide a temporary loading pressure, exercise caution when removing the actuator to prevent damage to the valve stem or piston rod.

1. Disconnect the actuator tubing from the pressure connections on the upper/lower head and outer spring cartridge (keys 1/9 and 23) and positioner.

Note

Refer to the appropriate instruction manual for any maintenance or adjustments that need to be made on the positioner.

⚠ WARNING

To avoid personal injury due to the sudden uncontrolled movement of parts, do not loosen the stem connector hex nuts when the stem connector has spring force applied to it.

2. Break the stem connection by removing hex nuts (key 62), studs (key 63) and lock washers (key 10) from the stem connector (key 18).
3. Depending on the yoke boss size, there is either a yoke locknut or bonnet-to-actuator bolting securing the actuator to the valve bonnet. Remove whichever is present.
4. **For 685SE Actuators:** Using the lifting points along the outside perimeter of the outer spring cartridge (key 23), attach appropriate rigging gear to both lifting points and lift the actuator away from the valve bonnet and stem.
For 685SR Actuators: Thread two lifting eyes into the free ports on the upper head (key 1) 180 degrees apart. Reference tables 4 and 5 for approximate weights of the actuator to select an appropriate lifting eye. Attach appropriate rigging gear to both lifting eyes and lift the actuator away from the valve bonnet and stem.
5. Refer to the Actuator Mounting section of this manual for instructions on mounting and installing the actuator onto a valve.

685SE Seal and O-ring Replacement

The following procedure is for the replacement of the internal piston seals, bearing seals, and O-rings.

1. Remove the lower head (key 9) from the yoke (key 21) by removing hex head cap screws (key 20) and lock washers (key 10).

2. Loosen tie bolt hex nuts (key 11) in a crisscross pattern. Remove tie rod hex nuts and lock washers (key 10).
3. Remove lower head (key 9) from cylinder (key 4) and place the O-ring side down onto wooden blocks or other material that will not scratch or gouge the lower head.
4. Extract bearing assembly (keys 12, 13, 14, and 15) from lower head (key 9) by removing the bearing retaining ring (key 16).
5. Remove the piston wiper seal (key 15), O-ring (key 13), and quad seal (key 12) from the bearing (key 14).
6. Clean bearing (key 14) with a light degreaser, if needed.
7. Lightly grease the new O-ring (key 13) and quad seal (key 12), then install onto bearing (key 14). Without grease, install a new piston wiper seal (key 15) onto the bearing.
8. Reinstall bearing assembly (keys 12, 13, 14, and 15) into lower head (key 9) and secure in place with the bearing retaining ring (key 16).
9. Remove the O-ring (key 2) from the lower head (key 9) and clean the groove with a light degreaser.
10. Lightly grease the new O-ring (key 2) and install on lower head (key 9).
11. Remove tie bolts (key 3) from upper head (key 1).
12. Lift piston assembly (keys 5, 6, 7, 17, and 19) out from cylinder (key 4) and place on a flat surface.
13. Remove the wear ring (key 6) and quad seal (key 7) from the piston (key 5).
14. Thread locking compound is applied to the threads by the manufacturer during initial assembly. As a result, disassembly will require heating to loosen the thread locking compound. To remove the piston rod O-ring (key 19), heat the piston assembly using a torch and unthread the piston rod (key 17) from the piston (key 5).
15. After the piston rod (key 17) has completely cooled, remove the piston rod O-ring (key 19). Clean the piston rod O-ring groove with a light degreaser. Lightly grease a new piston rod O-ring and install onto the piston rod.
16. Reinstall piston rod (key 17) onto piston (key 5) using thread locking compound.
17. Clean piston seal grooves. Install new lightly greased quad seal (key 7) onto piston (key 5).
18. Without grease, trim to length and then install a new wear ring (key 6).
19. Lift cylinder (key 4) vertically and place on a flat surface. Take extra precaution to avoid scratching or gouging the inner diameter of the cylinder.
20. Remove O-ring (key 2) from the upper head (key 1) and clean the seal groove. Install lightly greased new O-ring into upper head seal groove.
21. Install cylinder (key 4) onto upper head (key 1), making sure the O-ring (key 2) does not move out of its groove.
22. Carefully install the piston assembly (keys 5, 6, 7, 17, and 19) into cylinder (key 4), making sure all seals and O-rings stay in place on the outside diameter of the piston (key 5).
23. Install tie bolts (key 3) into upper head (key 1).
24. Carefully install lower head (key 9) onto cylinder (key 4), taking care not to damage threads on the tie bolts (key 3). Be sure the O-ring (key 2) is in place during this step.
25. Install lock washers (key 10) and tie bolt hex nuts (key 11) onto tie bolts (key 4). Torque in a crisscross pattern according to table 8.
26. Refer to the Actuator Mounting section of this manual for instructions on mounting and installing the actuator onto a valve.

Table 8. Tie Bolt Torque

BOLT DIAMETER	TORQUE	
	N • m	lbf • ft
1/4-20	8	6
5/16-18	15	11
3/8-16	26	19
7/16-14	39	29
1/2-13	60	44
9/16-12	84	62
5/8-11	115	85
3/4-10	198	146
7/8-9	313	231
1-8	445	328
1-1/8-7	662	488

685SR Seal and O-ring Replacement

The following procedure is for the replacement of the internal piston seals, bearing seals, and O-rings.

1. Complete Actuator Removal procedures above. Using the same rigging and lifting points as in the Actuator Removal section, place the actuator upright with the yoke (key 21) flat against the ground. Place either a flat piece of plywood or cloth under the yoke to protect against damage. Using straps, secure the actuator to a solid structure to prevent it from falling over.
2. Loosen tie bolt hex nuts (key 11) in a crisscross pattern. Remove tie rod hex nuts and lock washers (key 10).
3. Using the same lifting eyes as in the Actuator Removal procedure, lift or hoist the upper head (key 1) off of the cylinder (key 4). Place the upper head onto wooden blocks or other material that will not cause damage with the O-ring side facing up.
4. Remove O-ring (key 2) from the upper head (key 1) and clean the seal groove. Install lightly greased new O-ring into upper head seal groove.
5. Remove tie bolts (key 3) from lower head (key 9).
6. Thread a suitable lifting eye into the free port on the top of the piston rod (key 17).
7. Lift or hoist the piston assembly (keys 5, 6, 7, 17, and 19) out from cylinder (key 4) and place on a flat surface upside down.
8. Remove the wear ring (key 6) and quad seal (key 7) from the piston (key 5).
9. Thread locking compound is applied to the threads by the manufacturer during initial assembly. As a result, disassembly will require heating to loosen the thread locking compound. To remove the piston rod O-ring (key 19), heat the piston assembly using a torch and unthread the piston rod (key 17) from the piston (key 5).
10. After the piston rod (key 17) has completely cooled, remove the piston rod O-ring (key 19). Clean the piston rod O-ring groove with a light degreaser. Lightly grease a new piston rod O-ring and install onto the piston rod.
11. Reinstall piston rod (key 17) onto piston (key 5) using thread locking compound.
12. Clean piston seal grooves. Install new lightly greased quad seal (key 7) onto piston (key 5).
13. Without grease, trim to length and then install a new wear ring (key 6).
14. Lift cylinder (key 4) vertically and place on a flat surface. Take extra precaution to avoid scratching or gouging the inner diameter of the cylinder.
15. Remove the O-ring (key 2) from the lower head (key 9) and clean the groove with a light degreaser.
16. Lightly grease the new O-ring (key 2) and install on lower head (key 9).
17. Extract bearing assembly (keys 12, 13, 14, and 15) from outer spring cartridge (key 23) by removing the bearing retaining ring (key 16).

18. Remove the piston wiper seal (key 15), O-ring (key 13), and quad seal (key 12) from the bearing (key 14).
19. Clean bearing (key 14) with a light degreaser, if needed.
20. Lightly grease the new O-ring (key 13) and quad seal (key 12), then install onto bearing (key 14). Without grease, install a new piston wiper seal (key 15) onto the bearing.
21. Reinstall bearing assembly (keys 12, 13, 14, and 15) into outer spring cartridge (key 23) and secure in place with the bearing retaining ring (key 16).
22. Install cylinder onto lower head (key 9), making sure the O-ring (key 2) does not move out of its groove.
23. Carefully install piston assembly (keys 5, 6, 7, 17, and 19) into the cylinder (key 4) using the lifting eye previously used for removal. Ensure all seals and O-rings stay in place on the outside diameter of the piston (key 5) during installation.
24. Install tie bolts (key 3) into lower head (key 9).
25. Carefully install upper head (key 1) onto cylinder (key 4) using the lifting eyes previously used for removal. Take care not to damage tie bolt (key 3) threads and ensure that the O-ring (key 2) is in place during this step.
26. Install lock washers (key 10) and tie bolt hex nuts (key 11) onto tie bolts (key 4). Torque in a crisscross pattern according to table 8.
27. Refer to the Actuator Mounting section of this manual for instructions on mounting and installing the actuator onto a valve.

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, refer to the serial number found on the actuator nameplate.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts Kits

Includes all soft seals and O-rings required for seal and O-ring replacement in standard operating temperature constructions. Refer to figures 3 and 4.

Introduction

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for the Fisher 785C piston actuator. Refer to separate instruction manuals for information regarding other equipment and accessories used with these actuators.

Do not install, operate, or maintain 785C actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Table 1. Specifications

Operating Pressure⁽¹⁾

Minimum: 2.7 barg (40 psig)

Maximum Allowable: 10.3 barg (150 psig)

Consult your [Emerson sales office](#) for supply pressures under 2.7 barg (40 psig)

Travel⁽²⁾

16 mm (0.625 inch) through 610 mm (24 inch)
See table 2 and 4

Thrust Capabilities

See table 3, 6, and 7

Stroking Speeds

Varies with actuator size, spring, travel, and supply pressure. If stroking speed is critical, consult your Emerson sales office.

Piston Diameter and Area⁽²⁾

Available diameters range from 280 to 685 mm (11 to 27 inches).

See table 2, 4, and 5

For additional sizes, contact your Emerson sales office.

Operative Temperature Limits⁽³⁾

Standard: -20 to 100°C (-4 to 212°F)

Low Temperature Options:

-40 to 100°C (-40 to 212°F) or

-60 to 100°C (-76 to 212°F)

High Temperature Option:

-20 to 200°C (-4 to 392°F)

Yoke Boss and Valve Stem Diameter

Standard: ■ 90 mm (3-9/16 inch) yoke boss with 19 mm (3/4 inch) stem ■ 127 mm (5 inch) yoke boss with 25.4 mm (1 inch) stem ■ 127 mm (5H) yoke

boss with 32 mm (1-1/4 inch) stem ■ 178 mm (7 inch) yoke boss with 51 mm (2 inch) stem

High Performance: ■ 127 mm (5H) yoke boss with 32 mm (1-1/4 inch) stem ■ 178 mm (7 inch) yoke boss with 51 mm (2 inch) stem

Pressure Connections

Standard: 3/4 NPT

Optional: 1 and 1-1/4 NPT

Instrument Mounting

Standard mounting kits are available for use with FIELDVUE DVC6200 Series digital valve controllers up to 610 mm (24 inch) travel. High performance mounting kits are available for travel above 203 mm (8 inch).

Construction Materials⁽⁴⁾

Part	Material
Cylinder	Carbon Steel
Nameplate and Travel Scale	Stainless Steel
Piston	Carbon Steel
Piston Rod	Stainless Steel
Stem Connector	Carbon Steel or Stainless Steel
Tie Rod	Carbon Steel or Stainless Steel
Upper/Lower Heads	Carbon Steel
Yoke	Carbon Steel

Lifting Point Load Ratings

See table 8 and figure 2

Options

- Top mounted handwheel
- Side mounted handpump
- Pneumatic fail mode via Fisher 377 trip valve
- Volume boosters

Optional Certifications⁽⁵⁾

- Pressure Equipment Directive (PED) 2014/68/EU and Machinery Directive 2006/42/EC
- ATEX Group II Category 2 Gas and Dust
- Customs Union Technical Regulations (CUTR) 010/2011 and 012/2011
- Safety Instrumented System, SIL 3 Capable
- Inspection Documents EN 10204 3.1 Certificate

1. The pressure/temperature limits in this bulletin and any other applicable standard or code should not be exceeded.

2. Consult your Emerson sales office for longer travels or larger cylinder diameters. The Fisher 585C family of actuators can be used for smaller travels or cylinder diameters.

3. Standard temperature -20 to 100°C (-4 to 212°F) and -40 to 100°C (-40 to 212°F) are PED 2014/68/EU and 2006/42/EC compliant. The low ambient temperature option, -60 to 100°C (-76 to 212°F) is not PED compliant. The high temperature option, if used in conjunction with ATEX, is limited to 135°C (275°F).

4. Full stainless steel constructions are available upon request.

5. Refer to the product nameplates to determine which certifications each actuator construction possesses

Description

The 785C product lines encompass medium to large spring-return single-acting and double-acting piston actuators that provide accurate, high thrust output for short to long travel applications. These actuators are designed for use with a variety of medium to large Fisher sliding-stem control valves.

The single-acting actuators feature an internal bias spring that forces the actuator piston rod to extend or retract upon a loss of supply pressure, thereby ensuring a fail-closed or fail-open mode of operation. This effectively eliminates the need for a trip valve and volume tank in most constructions.

Specifications

Specifications for the 785C line of piston actuators are shown in tables 1 to 8. Refer to the nameplate affixed to the actuator yoke for specifications specific to individual constructions.

Principle of Operation

785C piston actuators utilize a pneumatically controlled piston that moves inside of a cylinder to generate thrust. A seal contained on the circumference of the piston provides a seal between the top and bottom of the cylinder, preventing supply pressure leakage.

785C single-acting or double-acting spring-return piston actuators utilize a spring below the piston (outside the pressurized chamber) that will drive the piston rod upon a loss of supply pressure. This fail action will result in forcing an attached control valve to either fail-open or fail-closed. The fail action of 785C double-acting springless piston actuators relies on pneumatic system such as system with Fisher 377 trip valve.

From an equilibrium state, the actuator operates by reacting to a force unbalance that is created by change of supply pressure on one side of the piston for single-acting, or a change of differential pressure between each side of the piston for double-acting. This moves the piston up or down, and results in a repositioning of the attached control valve. Travel can be adjusted using travel limits within a valve positioner, which limit the travel range of the actuator. The option of a hard travel stopper is also available, consult your [Emerson sales office](#) for details. The optional manual override does not have the ability to act as a hard travel stop.

An optional manual override (top mounted handwheel or side mounted handpump) is capable of extending or retracting the actuator manually and can be engaged at any position from full open to full close. The top-mounted handwheel utilizes an engagement lever that couples the handwheel and piston rod. The handpump has a hydraulic cylinder attached to the piston rod. This enables the handpump to operate the actuator manually, unless the handpump is set to bypass position.

1. Welded eyelets for horizontal lifting are only available for the 785C Spring Return.
2. Vertical lifting loads are applicable to both the 785C Springless and Spring Return.

Figure 2. Lifting Angle

Installation

Key numbers in this procedure are shown in figures 9 to 28, unless otherwise indicated.

⚠ WARNING

To avoid personal injury or property damage caused by cylinder fracture as a result of piston impact, install the stem connector securely before supplying pressure to the positioner. Use only a regulator-controlled air supply to move the actuator piston so that you can install the stem connector. Do not use the positioner to move the actuator piston before installing the stem connector.

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

If installing into an existing application, also refer to the warning at the beginning of the Maintenance section in this manual.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

To avoid personal injury or property damage caused by bursting of pressure-retaining parts, be certain the cylinder pressure or other pressure ratings do not exceed the limits listed in table 1. Use pressure-limiting or pressure-relieving devices to prevent cylinder pressure or other pressures from exceeding these limits.

To avoid personal injury or equipment damage, use proper lifting and rigging practices while lifting the actuator or valve/actuator assembly. For all mounting procedures use an adequately sized chain, sling, hoist, or crane to handle the

actuator and any attached accessories and/or valve. Use caution during lifting and handling to prevent slippage, swinging, faulty equipment connections, or sudden shock loads.

NOTICE

Special care must be taken when installing an actuator in a horizontal service orientation. To avoid cantilever loads on the valve stem and yoke, it is the customer's responsibility to ensure proper support for a horizontal actuator.

The actuator may be installed in any orientation, but normal installation is with the actuator vertical above the valve.

If using a manual override in double acting application, a bypass valve should be furnished, allowing balance the pressure within both sides of the piston before operating the manual override.

If using a manual handpump, the handpump must be installed vertical above the valve (see figure 7).

If the supply source is capable of exceeding the maximum actuator operating pressure or instrument supply pressure, appropriate steps must be taken during installation to protect the instrument and all connected equipment against overpressure.

When an actuator and control valve are shipped together as a control valve assembly, the actuator is normally mounted on the valve. Follow the valve instructions when installing the valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the actuator mounting procedures in this instruction manual. Refer to the individual product instruction manuals for the installation or mounting of a FIELDVUE DVC6200 digital valve controller.

If the actuator is being installed without a positioner, the cylinder loading pressures should be supplied through a 4-way solenoid valve or a switching valve.

Pressure connections are located on top of the pneumatic cylinder end flange (key 2210) and on the side of the pneumatic cylinder head flange (key 2201).

- The supply pressure medium should be clean, dry filtered air. If the supply source is capable of exceeding the maximum actuator operating pressure or positioner supply pressure, appropriate steps must be taken during installation to protect the positioner and all connected equipment against over pressurization.
- The control valve should be located where it will be accessible for servicing. Space should be left above and below the control valve to permit removal of the actuator and valve plug.

Actuator Earth Grounding

All Fisher 785C series actuators are provided with a threaded actuator earth grounding interface on the yoke (spool) for the earth connection as shown in the figure 3.

Note

Proper connection to the earth grounding interface is required for compliance with ATEX regulations.

Figure 3. Actuator Earth Grounding Interface

Three-Way Valve Applications Note

In three-way valve applications where the actuator fully strokes at a frequency of once per minute or faster, and the stroking speed is rapid (less than 0.5 seconds per stroke), there is a possibility that the stem can fracture at the plug if the actuator cylinder pressure is greater than 5.5 bar (80 psig). This can cause loss of control of process fluid and further damage to the actuator. Considerations should be given to the use of high-strength, fatigue-resistant stem materials in these applications.

⚠ WARNING

To avoid loss of control of process fluid and subsequent personal injury or property damage caused by bursting of pressure-retaining parts, be sure the cylinder pressure does not exceed 5.5 bar (80 psig) in high cycle-rate, fast stroking speed, three-way valve applications.

Manual Override

The actuator can be equipped with a manual override. The manual override can be executed with a Manual Handwheel or a Manual Hydraulic Pump which can operate the actuator.

Manual Handwheel Operation

If manual operation is required for actuator sizes 280, 335, and 385 a manual handwheel should be equipped as standard construction.

NOTICE

To avoid damage to actuator parts and difficult operation of actuator handwheels, open the bypass valve before using a handwheel. Do not disengage the handwheel if the spring thrust is not balanced by pneumatic load for spring return actuator.

A bypass assembly is furnished only when an actuator with manual override is specified, see figure 4. The bypass assembly allows the pressure to equalize on either side of the actuator piston, so that the manual override can be used to position the control valve. Flow through the bypass tubing is controlled by an angle needle valve, which is operated manually. This valve should be closed when air pressure is being used to operate the actuator.

Figure 4. Bypass Valve Examples for Double-Acting 785C Actuator with Manual Override

GH14579, sheet 1

GH14579, sheet 3

The following steps reference figure 5 and 6. Refer to table 6 for handwheel specifications.

Figure 5. Top Mounted Manual Handwheel

Figure 6. Top Mounted Manual Handwheel Engagement/Disengagement Instruction Label

1. Engage the manual override by rotating its handle, reference figure 5. Note that there is only one position (at 360° rotation of the handwheel) where the handle will correctly engage the manual operation. To reach that position during the rotation of the handle, slowly rotate the handwheel until the correct position, as indicated on the warning plate shown in figure 5.
2. Turn the handwheel of the manual override clockwise to close, or counterclockwise to open, as indicated on the instruction label shown in figure 6.
3. Check the correct operation of the actuator by monitoring the movement of the travel indicator.
4. Once manual operation is completed, the bypass valve should be close and remain shut off during pneumatic supply air operation.
5. Ensure the unbalanced thrust, such as spring return actuator spring thrust, is balanced by applying a pneumatic load and disengage the manual handwheel by rotating the handle as shown on the instruction plate. This allows the actuator to be operated by the pneumatic supply.

If it is necessary to keep the valve in its position and if the pneumatic supply is not restored yet, do not disengage the handwheel.

For spring return actuator, if it is not necessary to keep the valve in its position and if the pneumatic supply is not restored yet, in order to disengage the handwheel, turn the handwheel to the end which spring would fully release without applying any thrust to the handwheel, to get an easy disengagement of the handwheel.

Manual Hydraulic Handpump Operation

If manual operation is required, actuator sizes 435, 485, 535, 585, 635, and 685 should be equipped with a manual handpump as standard construction.

Note

The manual handpump control unit must be installed in vertical up direction per figure 7. For application requiring actuator horizontal installation, a special design handpump support and hydraulic tubing must be used to install handpump in vertical up direction per figure 7. Contact your Emerson sales office for further information of manual handpump for actuator horizontal installation.

Figure 7. Handpump Orientation

GH15114 sheet 1

A bypass assembly is furnished only when an actuator with manual override is specified. The bypass assembly allows the pressure to equalize on either side of the actuator piston, so that the manual override can be used to position the control valve. Flow through the bypass tubing is controlled by an angle needle valve, which is operated manually. This valve should be closed when supply pressure is being used to operate the actuator.

The following steps are referenced in figures 8, 9, and 10. Refer to table 7 for handpump specifications and figures 11 through 17 for handpump schematics and more detail instructions.

1. Select “Manual Opening” or “Manual Closing” by rotating the Engagement/Disengagement handle as indicated on the instruction plate from pneumatic operation “REMOTE” mode.
2. Actuate the handpump according to figure 11 through 17 handpump schematic detail instructions until the desired position of the actuator is reached.
3. Check the correct operation of the actuator through the visual travel indicator.

- Once manual operation is completed, rotate the handle to the "REMOTE" position, as indicated on the instruction plate in figure 8, to disengage the manual operator. Follow figure 11 through 17 handpump schematic detail instructions to allow the "REMOTE" operation with the pneumatic supply. Once manual operation is completed, the bypass valve should be close and remain shutoff during pneumatic supply air operation.

| 395 | RELIEF VALVE |

Actuator Mounting

The following procedure describes how to mount a 785C actuator on a push down to close valve so that the piston rod to valve plug stem connection allows full travel and proper shutoff. Key numbers referenced in the following steps are shown in figures 24 through 38 and 48. If you purchase a 785C actuator for field installation on a control valve, mount the actuator on the valve and secure it to the bonnet with the bonnet-to-actuator bolts. The stem connection should then be made up to clamp the actuator stem and valve plug stem together to provide proper valve travel.

⚠ WARNING

When moving the piston rod with loading pressure applied, exercise caution to keep hands and tools out of the piston rod travel path. If the loading pressure is accidentally disconnected, personal injury and property damage is possible if something is caught between the piston rod and other control valve parts.

NOTICE

The 785C spring extend actuator spring load will force the piston rod to extend out of the cylinder, and it can come into contact with the valve stem during actuator mounting.

If the valve stem is allowed to remain in the up position (towards the actuator) during mounting, it can interfere with the actuator mounting, possibly damage valve stem threads or bend the valve stem. Be sure the valve stem is pushed down (into the valve body), away from the actuator while mounting.

To avoid damaging the valve plug seating surfaces, do not rotate the valve plug while it is seated. Also avoid damage to the valve plug stem by careful use of tools during travel adjustment.

1. Using the given lifting eye bolts (key 2215), hoist the actuator vertically oriented. Slowly lower it over the valve taking care not to contact the stem in manner that could cause damage.
2. Once the actuator is seated on the bonnet yoke, install the studs through the yoke mounting plate. Install the nuts and tighten to the appropriate torque as specified in the applicable valve instruction manual.

⚠ CAUTION

Before pressurizing the cylinder, ensure the plastic plugs are removed from the pneumatic cylinder and replaced with appropriate metal plugs or other pressure-retaining devices.

3. Starting with the piston (key 2206) at the top of the pneumatic cylinder, manually, or with air pressure, extend the piston rod (key 2350 or 2402) to the specified valve travel.
4. With the valve plug on the seat, attach the valve stem connector (key 4301) by inserting the socket head cap screws (key 4302), clamping the piston rod (key 2350) to the valve stem. Make sure to attach the travel indicator (key 5000) and anti-rotator plate (key 4850) if supplied. Confirm proper operation and check travel, travel indicator adjustment, etc. before placing the actuator into operation.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced when necessary. The frequency of inspection and replacement depends on the severity of service conditions.

⚠ WARNING

Avoid personal injury and property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any spring pre-compression.
- Use lock-out procedures to be sure the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Instructions are given below for complete disassembly of the actuator, seal replacement, and O-ring replacement. When inspection or repair is necessary, disassemble the actuator only as far as is required to accomplish the job. Key numbers referenced in the following steps are shown in figures 18 through 53.

Actuator Removal

The following procedure is for the removal of the actuator from the valve.

⚠ WARNING

To avoid personal injury or equipment damage, use proper lifting and rigging practices while lifting the actuator assembly.

To avoid personal injury due to the sudden uncontrolled movement of parts, do not loosen the stem connector hex nuts when the stem connector has spring force applied to it.

1. Ensure the valve and actuator are de-energized (mechanical, pneumatic, and electric) and appropriately isolated. Disconnect the actuator tubing from the pressure connections on the pneumatic cylinder head flange and end flange (key 2201 and 2210) and positioner. Provisions may need to be made to the actuator and spring if the design is spring extended.

For 785C Spring Extend actuator: It may be necessary to apply a temporary loading pressure to the bottom cylinder pressure connection to move the piston rod away from the valve stem during removal. If it is not possible to provide a temporary loading pressure, exercise caution when removing the actuator to prevent damage or personal injury.

2. Disconnect the stem connection by removing socket head cap screws (key 4302) from the valve stem connector (key 4301).

3. Remove the bonnet-to-actuator bolting securing the actuator to the bonnet. Make sure the actuator is supported and secured by other means prior to loosening nuts.
4. Using the lifting points provided (key 2215), hoist the actuator vertically taking care not to contact the stem in a manner that would cause damage.

Disassembling the Pneumatic Cylinder

The following procedure is for the replacement of the internal piston seals, bearing seals, and O-rings (see figure 19):

1. Complete Actuator Removal procedures per the applicable section of this instruction manual. Ensure the actuator is de-energized and isolated from the process.
2. Loosen the tie-rod hex nuts (key 2212) in a crisscross pattern to remove the pneumatic cylinder tie rod bolts (key 2213).
3. Remove the top cylinder end flange (key 2210) using the lifting lugs.
4. Remove the tie rods (key 2213). Remove the cylinder (key 2209) from the head flange (key 2201).

For a **partial replacement** of the pneumatic cylinder seals (namely, to replace all the seals with the exception of the head flange seal, (key 2102, 2107 and 2202), proceed to the Replacing Pneumatic Cylinder Seals section .

For complete **total replacement** of the pneumatic cylinder seals (namely, to replace all the seals), the pneumatic cylinder disassembly procedure proceed to step 5.

5. Unscrew the piston (key 2206) from the actuator stem using the two threaded holes (for actuator sizes 280 - 435 thread size is M10; for sizes 485 - 685 thread size is M16) by rotating counter-clockwise. Then lift and remove the piston from the actuator stem. Retain the washer (key 2205) located beneath the piston on to the stem. This operation is facilitated by the presence of threaded holes (figure 18).
6. Loosen and remove the fasteners holding the head flange (key 2201, figure 18 and 21).
7. Lift and remove the head flange (key 2201) from the spring can of 785C Spring Return Actuator or yoke of 785C Springless Actuator.

Figure 18. 785C Pneumatic Cylinder Components

Figure 19. 785C Actuator Pneumatic Cylinder Components Disassembly Sequence

Replacing the Pneumatic Cylinder Seals

When the pneumatic cylinder is totally disassembled, all the seals can be replaced referencing figures 18, 34, 35, and 36. Pneumatic cylinder seals might include piston rod seal (key 2202), end flange seal (key 2204), piston sliding ring (key 2207), piston outside seal (key 2208), scraper ring (key 2102), washer (key 2106), gasket (key 2107), O-ring (key 2222) (only for with manual handpump).

1. Thoroughly clean the slots and housings of seals and sliding ring; lubricate with protective oil or with a thin film of grease. Inspect all parts, including the piston rod (key 2350) and cylinder tube (key 2209), for damage and wear.
2. Put the seals and sliding ring accurately in place on the relevant component, being careful that the material does not get pinched or damaged.
3. Grease and lubricate the seals in their housings and the sliding ring. See table 11 for recommended lubricants.

Figure 20. Typical Sectional View of 785C Spring Return Actuator Pneumatic Cylinder Seals

NOTE: KEY 2222 PART NOT SHOWN (ACTUATOR WITH HANDPUMP ONLY)

Figure 21. Threaded Holes in Pneumatic Cylinder

Assembling the Pneumatic Cylinder

The cylinder is reassembled by following in reverse order the sequence described in section Disassembling the Pneumatic Cylinder. The screws must be tightened properly. Refer to table 10.

If only a partial replacement of the pneumatic cylinder seals has been performed, the pneumatic cylinder assembly procedure starts from step 3.

1. Ensure the seals (key 2102, 2107 and 2202) of the head flange (key 2201) have been replaced, lubricated, and are properly seated.
2. Install the head flange (key 2201) on to the spring cylinder (in case of 785C spring return actuator) or on to the yoke (in case of 785C springless actuator).
3. Place the washers (key 2106).
4. Lubricate bolts (key 2105) and torque to values given in table 10.
5. Ensure the seal (key 2204) of the head flange (key 2201) is replaced, lubricated, and properly seated.
6. Place the washer (key 2205) on the stem. Thread the piston (key 2206) on to the stem. Rotate clockwise until it seats on the piston then turn another 1/4 turn.
7. Ensure the seal and gasket (key 2207 and 2208) of the piston (key 2206) are replaced and properly seated. Make sure the seal is well lubricated.
8. Lift the cylinder (key 2209) and put it back in place by performing the operations below:
 - a. Thoroughly clean the cylinder (key 2209) inner surface and ensure the surface nor the chamfers are damaged.
 - b. Lubricate the entire inner surface and chamfers.
 - c. Slide the cylinder (key 2209) onto the piston taking care not to damage the cylinder inner surface, piston seal (key 2208), gasket (key 2207) and the head flange seal (key 2204).
 - d. The full mating surface of the cylinder (key 2209) should rest against the head flange (key 2201). The cylinder (key 2209) is not provided with screw interfaces for handling purposes. Use padded clamps or jaws to prevent damaging.
9. Ensure the seal (key 2204) of the top end flange (key 2210) is replaced and properly seated.
10. Assemble the end flange (key 2210) by centering it with the inside diameter of the cylinder (key 2209), taking care not to damage the seal (key 2204). The full surface of the end flange should rest against the mating cylinder (key 2209) face. Align the top and bottom end flange (key 2210) tie rod holes.
11. Screw each tie rod (key 2213) back in its housing on the head flange.
12. Install the washers (key 2211) and tighten the nuts (key 2212) on the tie rods (key 2213) in a crisscross pattern to the appropriate torque per table 10.
13. Refer to the Actuator Mounting section of this manual for instructions on mounting and reinstalling the actuator onto the valve. As best practice, check for leakage after installation for all sealing surfaces.

Table 10. Tie Bolt Torque⁽¹⁾

Check and Restore Manual Handpump Hydraulic Oil Level

During the actuator operation, the oil tank has to be closed (not in connection with the atmosphere). To avoid cavitation, it is necessary to proceed as follows to check the oil tank oil level.

Refer to figure 45 and 46 unless otherwise indicated:

1. Remove the oil tank dipstick (key 2751-1.7).
2. Move the actuator into the open position.
3. Check that the oil level in the oil tank (key 2751-4) corresponds to the maximum level mark of the dipstick (figure 22).
4. With the dipstick still removed, move the actuator to the closed position using the handpump.

5. Reinstall and tighten the dipstick.

To replace or add oil, proceeding as follow:

1. Remove the dipstick (key 2751-1.7) from the tank cover (key 2751-22).
2. To drain oil, unscrew the plug (key 2751-27) and remove the washer (key 2751-9).

Note

If dirt and/or sludge is found in the oil drained from the tank, before filling with new oil in the tank, disassemble the oil tank tube by unscrewing the two cap nuts (key 2751-2) and clean the internal surfaces of the tank. If necessary replace the tank O-ring (key 2751-21).

3. Reinstall the washer (key 2751-9) and tighten the plug (key 2751-27) onto the plate (key 2751-11). Pour the new oil into the tank through the dipstick hole on the cover (key 2751-22).
4. Reinstall and tighten the dipstick (key 2751-1.7).
5. If the oil in the tank is below the minimum level mark (figure 22) add additional oil per table 12.

Figure 22. Hydraulic Manual Handpump Dipstick Oil Level Mark

Table 12. Handpump Hydraulic Oil

Lower Temperature	Hydraulic Oil
Standard: -20 to 100 °C (-4 to 212 °F)	AGIP ARNICA 22 or equivalent oils (SHELL TELLUS PLUS 22, CHEVRON HYDRAULIC OIL AW ISO 22, MOBIL DTE22, EXXON UNIVIS N22, EQUIVIS ZS22, BP ENERGOL HLP-HM22, CASTROL DYSPIN AWS22)
Low Temperature Options: -40 to 100°C (-40 to 212°F) or -60 to 100°C (-76 to 212°F)	Aeroshell Fluid 41

Disassembling the Handpump Hydraulic Cylinder

WARNING

Refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

If there are leaks in the 785C Actuator manual handpump hydraulic cylinder, a malfunction in the mechanical components, or in case of scheduled preventive maintenance, the actuator must be disassembled, and the seals must be replaced with reference to the sectional drawings and following procedures:

1. Deenergize the actuator and valve assembly.
2. Drain the hydraulic fluid from the piston via the drain ports.
3. Remove the nuts (key 2714) from the tie rods (key 2713) at the end flange (key 2712) side.
4. Slide off the end flange and the hydraulic cylinder (key 2711).
5. Slide off the piston rod (key 2706) from the head flange (key 2701).

Handpump Hydraulic Cylinder Seals Replacement

1. Prior to reassembly check that the actuator components are in good condition.
2. Lubricate all mating surfaces with recommended lubricant (see table 11).
3. If the O-ring must be replaced, remove the existing one from its groove, clean the groove carefully and lubricate it with protective oil film. Assemble the new O-ring into its groove and lubricate.
4. Replace the O-rings (key 2708) of the head flange (key 2701).
5. Replace the O-ring (key 2708) of the end flange (key 2712).

For replacement of piston rod seal ring (key 2705) and of the O-ring (key 2704) proceed as follows:

1. Remove the existing PTFE seal ring (key 2705) and the O-ring (key 2704) from their groove.
2. Clean the groove carefully and lubricate.
3. Assemble the new O-ring (key 2704) into its groove and lubricate.
4. Assemble the new PTFE seal ring (key 2705) into the flange groove, on the rubber O-ring (key 2704), by bending it. Take care bend the seal the least amount required.
5. Enlarge the seal ring with your fingers to restore its round shape. Pay attention not to utilize any tools, which can damage the seal ring.

For replacement of piston rod seal ring (key 2710) and of the O-ring (key 2709) proceed as follows:

1. Remove the existing PTFE seal ring (key 2710) and the O-ring (key 2709) from their groove.
2. Clean the groove carefully and lubricate.
3. Assemble the new O-ring (key 2709) into its groove and lubricate.
4. Assemble the new PTFE seal ring (key 2710) on its rubber O-ring by introducing one side into the groove and then enlarge it with your fingers so as to seat it into the groove. Take care to enlarge it uniformly without any tools which could possibly damage it. The elastic memory of the of the PTFE the seal ring will allow the ring to shrink back to its previous dimension.

Handpump Hydraulic Cylinder Reassembling

1. Assemble the new gasket (key 2624) after cleaning the surfaces of pneumatic cylinder head flange (key 2210), spacer (key 2622) and head flange hydraulic (key 2701) which are in contact.

2. Assemble the head flange and tighten the screws (key 2621) to the recommended torque (see table 10).
3. Clean and lubricate the piston rod (key 2706) surface, particularly that of the bevel, and insert it into the head flange hole, taking care not to damage the PTFE seal ring (key 2705). The piston rod bevel has to enlarge the seal ring.
4. Carefully clean the inside of the tube (key 2711) and check that the entire surface, particularly that of the bevels, is not damaged. Lubricate the tube inside surface and the bevels at the ends.
5. Slide the tube onto the piston taking care not to damage the PTFE seal ring (key 2710). The tube bevel has to smoothly compress the seal ring. Take care to not damage the head flange O-ring (key 2708).
6. Assemble the end flange (key 2708) by centering it on the inside diameter of the tube, taking care not to damage the O-ring (key 2708).
7. Assemble the nuts (key 2714) onto the tie rods (key 2713). Tighten the nuts to the recommended torque per table 10, alternating between opposite corners.

Troubleshooting

Table 14. 785C Troubleshooting

Symptom	Common Possible Cause	Solution
Inadequate operation of actuator using handpump	Handpump control unit (key 2751) not in required vertical up orientation per figure 7	Contact your Emerson sales office to modify the handpump control unit into correct installation orientation per figure 7
	Handpump hydraulic oil level too low	Check and restore correct handpump hydraulic oil level
	Too much air within hydraulic cylinder	Contact your Emerson sales office to bleed the handpump hydraulic cylinder air
Pneumatic stroking speed too slow for actuator with handpump	Standard Stroke MHP handpump Engagement/Disengagement handle at “Manual Opening” or “Manual Closing” position	Set Standard Stroke MHP handpump Engagement/Disengagement handle to “REMOTE” position per figure 8 and the correct schematic figure 12, 14, or 15
	Fast Stroke MHQ handpump hydraulic cylinder bypass stop valve at close position	Open Fast Stroke MHQ handpump hydraulic cylinder bypass stop valve per the correct schematic in figure 11, 13, 16, or 17
	Flow restriction in hand pump or hydraulic system affecting actuator stroking speed	Contact your Emerson sales office to upgrade to 785C Fast Stroke MHQ handpump type 1 or type 2
	Flow restriction in pneumatic system affecting actuator stroking speed	Contact your Emerson sales office to investigate the stroking speed sizing problem
Single acting spring return actuator will not achieve full travel	Actuator venting port blocked	Clean venting side vent assemblies, e.g. Y602 vent
	Supply air pressure too low to fully extend/retract actuator	Increase supply air pressure back to actuator sizing required pressure
Actuator movement not smooth	Erratic, or jerky, actuator movement may indicate excessive actuator or valve friction	Contact your Emerson sales office to complete ValveLink scan of actuator and valve movement to identify if valve or actuator repair is required
Valve positioner out of calibration during fast stroking or high vibration	Severe application conditions affecting positioner or mounting kit	Contact your Emerson sales office to investigate the issue, and determine if upgrading to the high performance mounting kit is recommended

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, refer to the serial number. When ordering replacement parts, also specify the key number, part name, using the Parts List.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts List

Note

Contact your [Emerson sales office](#) for Part Ordering information.

Key	Description
1	785C Nameplate
2	Drive Screw
3	Travel Scale
4	Bushing
5	Vent Assembly
6	Nipple
7	Max Cylinder Pressure Warning Tag
8	Stem Connector Nuts
9	Bypass valve (see figure 4)
10	Tee (see figure 4)
11	Nipple (see figure 4)

1000 Nameplate Kits (figure 50)

Key	Description
1001	Linear Actuator Label
1002	Rivet
1003	Lifting Point Label
1004	Actuator Lifting Label

2000 Yoke (Spool) Assembly (figure 37)

Key	Description
2001	Yoke (Spool)
2002	Screw
2003	Screw
2004	Washer
2005	Screw
2006	Screw

2100 Repair Kit 785C Spring Return Assembly (figure 51 and 52)

Key	Description
2101	Scraper Ring Flange
2102*	Scraper Ring
2105	Screw
2106*	Washer
2107*	Gasket
2108	Washer
2109	Nut
2110	Screw

2200 Pneumatic Cylinder Assembly (figure 34, 35, and 36)

Key	Description
2201	Head Flange
2202*	O-Ring
2203	Bushing
2204*	O-Ring
2205	Washer
2206	Piston
2207*	Guide Sliding Ring, Piston
2208*	O-Ring
2209	Cylinder Tube
2210	End Flange
2211	Washer
2212	Nut
2213	Tie Rod
2214	Washer
2215	Eyebolt
2216	Plug
2217	End Stroke
2218	Screw
2219	Hub
2220	Screw
2221	Plug
2222*	O-Ring
2350	Piston Rod, Pneumatic Cylinder

2400 Spring Can (Spring Cartridge) Assembly (figure 38)

Key	Description
2401	Flange
2402	Rod
2403	Bushing
2404	Retainer Ring
2405	Piston Rod Guide Tube
2406	Flange
2407	Spring
2408	Spring
2409	Spring
2410	Calendered Sheet
2411	End Flange
2412	Lifting Eyelet
2413	Tube
2414	Plug

2600 Manual Handwheel Assembly (figure 39 and 40)

Key	Description
2601	Manual Handwheel
2601-1	Cover

Introduction

Scope of Manual

This instruction manual presents principle of operation, installation, maintenance, and parts list for the Fisher 1008 handwheel actuator (figure 1). Refer to separate instruction manuals for information about other equipment and accessories used with these actuators.

Do not install, operate, or maintain a 1008 handwheel actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

			32	1-1/4	75620	17000 ^(1,2)				
100	127	5	32	1-1/4	75620	17000 ^(1,2)	102	4	68.0	150
	178	7	51	2	251004	56000 ^(1,2)				

1. For S31600 (316 stainless steel) stems at 38°C (100°F).
2. Actuator limit.
3. Alternate 102 mm (4 inch) travel construction is available.

Description

The 1008 is a handwheel actuator for processes requiring a throttling valve that can be manually operated and set. The 1008 handwheel actuator is available in sizes 30, 40, 50, 80, and 100, and can be mounted on easy-e™ valves.

The 1008 handwheel actuator converts rotary motion of the handwheel to linear motion of the valve plug stem. Because the stem does not revolve, the valve plug contacts the same seating surface with each stroke. Sizes 40, 50, 80, and 100 include two thrust bearings to make rotation easier.

Turn the handwheel counterclockwise to open the valve regardless of valve plug action. All sizes of the 1008 handwheel actuator except size 100 are reversible following the Reversing Handwheel procedures in this instruction manual.

Specifications

Refer to table 1 for 1008 handwheel actuator specifications. Refer to the actuator nameplate for information about a specific actuator.

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

The 1008 handwheel actuator can be installed horizontally, vertically, or at any orientation in between. However, if supplied with a Tejax position indicator (see figure 6), the actuator must be installed in a horizontal position.

When an actuator and valve body are shipped together as a control valve assembly, the actuator is normally mounted on the valve. Follow the valve body instructions when installing the control valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the Actuator Mounting procedures.

Actuator Mounting

Key numbers refer to figure 2 for size 30, figure 3 for sizes 40 and 50, figure 4 for size 80 or figure 5 for size 100.

1. Place the actuator on the body bonnet and tighten the yoke locknut or the actuator mounting hex nuts.
2. Ensure the valve plug is on its seat.
3. Adjust the travel indicator scale (key 27) so that the two screws (key 19) are centered in the slots.
4. Screw the hex nuts (key 29) onto the valve plug stem and place the travel indicator disk (key 20) onto the stem above the hex nuts. Adjust the nuts until the travel indicator disk (key 20) points to the closed position on the scale.
5. Temporarily connect the valve plug stem to the stem connector assembly (key 24) and tighten the cap screws into the stem connector.
6. Use the handwheel (key 28) to move the valve plug into the fully open position, as indicated by the travel indicator disk (key 20) on the travel indicator scale (key 27).
7. Remove the stem connector assembly (key 24).
8. **Size 30:** Turn the handwheel (key 28) counterclockwise until the stem connector assembly (key 24) almost touches the top of the yoke;

Sizes 40, 50, and 80: Turn the handwheel (key 28) counterclockwise as far as it will go;

Size 100: Turn the handwheel (key 28) counterclockwise (for push-down-to-close valves) or clockwise (for push-down-to-open valves) as far as it will go.

NOTICE

Incomplete engagement of both valve stem and stem screw assembly (key 38) or size 100 power screw (key 5) in the stem connector can result in stripped threads or improper operation. Be sure that the length of each stem clamped in the stem connector is equal to or greater than the diameter of that stem.

9. Connect the valve plug stem to the stem connector assembly (key 24). Ensure that the bottom of the stem connector is touching or nearly touching the travel indicator disk (key 20). Tighten the stem connector (key 24) cap screws and lock the hex nuts (key 29) against the travel indicator disk (key 20) and stem connector.
10. Rotate the handwheel until the valve plug seats. Adjust the travel indicator scale (key 27) with two screws (key 19) so that the travel indicator disk (key 20) points to the closed position on the scale. Tighten the two screws.

Position Indicator Mounting

The Tejax position indicator is available on 1008 handwheel actuators, sizes 30, 40, and 50. It must be mounted in a horizontal position to function correctly. To set the position indicator:

1. Seat the valve plug.
2. Loosen the four screws holding the dial indicating unit in place.
3. Turn the dial until both hands are at the “Shut” (Zero) position.
4. Tighten the four screws.

The long pointer indicates fractions of a turn; the small pointer counts the number of full turns. The position indicator requires no lubrication.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced when necessary. The frequency of inspection and replacement depends on the severity of service conditions.

WARNING

Avoid personal injury from sudden release of process pressure. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Key numbers refer to figure 2 for size 30, figure 3 for sizes 40 and 50, figure 4 for size 80 or figure 5 for size 100.

Lubrication

The interior parts of a 1008 handwheel actuator should be lubricated on a regular schedule with a quality gear lubricant. The interior parts should also be lubricated whenever handwheel rotation becomes difficult.

Disassembly

Parts are subject to normal wear and must be inspected periodically. The following procedure describes actuator disassembly for general inspection and replacement.

For Size 30:

1. Remove the stem connector assembly (key 24).
2. Unscrew the set screw (key 13) from the yoke (key 26) and remove the steel balls (key 33) through the threaded hole.

Note

Be careful not to lose the ball (key 33) and spring (key 34) as the handwheel is removed.

3. Remove the handwheel (key 28) and stem screw assembly (key 38) from the yoke (key 26).

4. Unscrew the handwheel (key 28) from the stem screw assembly (key 38).

For Sizes 40 & 50:

1. Remove the stem connector assembly (key 24).
2. Unscrew the hex nut (key 14) and remove the washer (key 41) and lockwasher (key 42).

Note

Be careful not to lose the ball (key 33) and spring (key 34) as the handwheel is removed.

3. Remove the handwheel (key 28) from the stem screw assembly (key 38).
4. Loosen the set screw (key 13) and unscrew the bearing retainer (key 44).
5. Remove the stem screw assembly (key 38), thrust bearings (key 2), and nut (key 43) from the yoke (key 26).
6. Remove the nut from the stem screw assembly (key 38) to reach the remainder of the parts.

For Size 80:

1. Remove the stem connector assembly (key 24).
2. Unscrew the cap screws (key 12) and remove the gear case cover (key 11).
3. Unscrew the two socket head cap screws (key 37) and remove the retaining flange (key 35).
4. Remove the bearing and gear retainer (key 4) and the stem screw assembly (key 38).
5. Remove the thrust bearings (key 2) and worm gear (key 3) from the stem screw assembly (key 38).

Note

Be careful not to lose the ball (key 33) and spring (key 34) as the handwheel is removed.

6. To remove the worm shaft (key 9):
 - a. Remove the set screw from the handwheel cap (key 32).
 - b. Unscrew the handwheel cap and remove the handwheel (key 28).
 - c. Loosen the front (nearest to the threaded end of the worm shaft) set screw (key 10) and unscrew the front worm retainer (key 7).
 - d. Remove the ball bearing (key 8) and the worm shaft.

For Size 100:

1. Remove the stem connector assembly (key 24).
2. Unscrew the cap screws (key 12) and remove the gear case cover (key 11).
3. Remove the bearing and gear retainer (key 4) and the stem screw assembly (key 38).
4. Remove the thrust bearings (key 2) and worm gear (key 3) from the stem screw assembly (key 38).

5. To remove the worm shaft (key 9):
 - a. Remove the retaining ring (key 17).
 - b. Loosen the set screw (key 10) found on the handwheel (key 28) hub.
 - c. Remove the handwheel (key 28).
 - d. Loosen the set screw (key 10) and remove the front (nearest to the threaded end of the worm shaft) worm retainer (key 7), worm shaft (key 9), and front ball bearing (key 8).

Assembly

For Size 30:

1. Replace the spring (key 34) and ball (key 33) in the yoke (key 26).
2. Screw the handwheel (key 28) on the stem screw assembly (key 38).
3. Position the grooves in the handwheel (key 28) and yoke (key 26) to mate, then replace the steel balls (key 33) in the yoke through the threaded hole.
4. Replace the set screw (key 13).
5. Refer to the Installation procedures for instructions on connecting the valve plug stem to the actuator stem screw assembly (key 38).

For Sizes 40 & 50:

1. Replace the thrust bearings (key 2) and bearing seat (key 45) on the stem screw assembly (key 38). Screw the nut (key 43) on the stem screw assembly.

Note

Verify that the key (key 16) fits into the slot milled in the yoke (key 26) before reassembly.

2. Place the stem screw assembly (key 38) in the yoke (key 26).
3. Replace the bearing retainer (key 44), tightening so that the thrust bearings (key 2) move freely, then tighten the set screw (key 13).
4. Place the ball (key 33) in one of the indentations on the yoke, then place the handwheel (key 28) with the spring (key 34) over the ball.
5. Replace the lock washer (key 42) and washer (key 41) on the stem screw assembly (key 38) and tighten the hex nut (key 14).
6. Refer to the Installation procedures for instructions on connecting the valve plug stem to the actuator stem screw assembly (key 38).

For Size 80:

1. If the worm shaft (key 9) was removed during disassembly:
 - a. Replace the worm shaft with the ball bearing (key 8) and the front worm retainer (key 7).
 - b. Adjust the worm retainer to eliminate end play (movement of the worm shaft along its axis) while allowing adequate movement.

- c. Tighten the set screw (key 10) on the front retainer.
2. Replace the ball (key 33), handwheel (key 28), and handwheel cap (key 32), then tighten the set screw in the handwheel cap.
3. Replace one of the thrust bearings (key 2) in the gear case (key 1) making sure that the bearing race with the smaller inside diameter is adjacent to the worm gear web.
4. Screw the worm gear (key 3) on the stem screw assembly (key 38) and place them in the gear case (key 1).
5. Install the other thrust bearing (key 2) on the worm gear (key 3), making sure that the bearing race with the smaller inside diameter is adjacent to the worm gear web.
6. Replace the bearing and gear retainer (key 4).
7. Install the retaining flange (key 35) making sure that the key (key 36) fits in the slot on the retaining flange.
8. Coat the threads on the six set screws (key 13) with a hard-setting sealant. Adjust the six set screws to eliminate end play (movement along the axis of the stem screw assembly) in the thrust bearings, while allowing adequate movement.
9. Replace the gear case cover (key 11) and cap screws (key 12).
10. Replace the stem connector assembly (key 24).
11. Refer to the Installation procedures for instructions on connecting the valve plug stem to the actuator stem screw assembly (key 38).

For Size 100:

1. If the worm shaft (key 9) was removed during disassembly:
 - a. Replace the worm shaft with the ball bearing (key 8) and the front worm retainer (key 7).
 - b. Adjust the worm retainer to eliminate end play (movement of the worm shaft along its axis) while allowing adequate movement.
 - c. Tighten the set screw (key 10) on the front retainer.
2. Replace the key (key 16), handwheel (key 28), and retaining ring (key 17), then tighten the set screw in the hub of the handwheel.
3. Replace one of the thrust bearings (key 2) in the gear case (key 1) making sure that the bearing race with the smaller inside diameter is adjacent to the worm gear web.
4. Screw the worm gear (key 3) on the stem screw assembly (key 38) and place them in the gear case (key 1).
5. Install the other thrust bearing (key 2) on the worm gear (key 3), making sure that the bearing race with the smaller inside diameter is adjacent to the worm gear web.
6. Replace the bearing and gear retainer (key 4).
7. Replace the gear case cover (key 11) and fasten with the cap screws (key 12).
8. Adjust the six set screws (key 13) to eliminate end play (movement along the axis of the stem screw assembly) in the thrust bearings, while allowing adequate movement.
9. Replace the stem connector assembly (key 24).
10. Refer to the Installation procedures for instructions on connecting the valve plug stem to the actuator stem screw assembly (key 38).

Reversing Handwheels

Refer to the previous Disassembly and Assembly sections in this manual for additional instructions, as needed.

To reverse 1008 handwheel actuators sizes 30, 40, or 50, substitute left- or right-hand screw assemblies (key 38). The standard size 100 is not reversible. To reverse size 80, refer to figure 4 while performing the following procedures:

1. Loosen the three set screws (key 10) in the gear case (key 1) and handwheel cap (key 32).

Note

Be careful not to lose the ball (key 33) and spring (key 34) as the handwheel is removed.

2. Unscrew the handwheel cap (key 32) and remove the handwheel (key 28).
3. Remove the front worm retainer (key 7), ball bearing (key 8), and worm shaft (key 9).
4. Remove the back worm retainer (key 6) and ball bearing (key 8).
5. Screw the back worm retainer (key 6) and ball bearing (key 8) into the opening in the gear case (key 1) where the front worm retainer is located.
6. Replace the front worm retainer (key 7) and ball bearing (key 8).
7. Replace the spring (key 34) and ball (key 33), handwheel (key 28), and handwheel cap (key 32).
8. Tighten the three set screws (key 10) in the gear case (key 1) and handwheel cap (key 32).

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always mention this number when corresponding with your [Emerson sales office](#) regarding technical information or replacement parts.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

Scope of Manual

This instruction manual includes installation, adjustment, operation, maintenance, and parts information for the Fisher 1051 and 1052 Size 33 diaphragm rotary actuators (figure 1). Mounting adaptations F, G, H, and J are included in this manual. Instructions for the control valve, positioner, manual actuator, and other accessories are included in separate manuals.

Table 1. Specifications

Available Configuration

1051: For on-off service without a positioner or for throttling service with a positioner

1052: For on-off service without a positioner or for throttling service with or without a positioner

Standard Diaphragm Pressure Ranges

■ 0 to 1.2 bar (0 to 18 psig), ■ 0 to 2.3 bar (0 to 33 psig), ■ 0 to 2.8 bar (0 to 40 psig), and ■ 0 to 3.8 bar (0 to 55 psig)

Maximum Diaphragm Sizing Pressure^(1, 2)

3.8 bar (55 psig)

Maximum Diaphragm Casing Pressure^(1, 7)

4.5 bar (65 psig)

Maximum Valve Shaft Rotation

■ 90 degrees (adjustable through 60 degrees with integral travel stops)

Acceptable Valve Shaft Diameters, mm (Inches)

F and G mounting: ■ 12.7 (1/2), ■ 15.9 (5/8), or ■ 19.1 (3/4)

H mounting: varies—uses 22.2 mm (7/8 inch) output shaft with two flats

J mounting: ■ 9.5 (3/8), ■ 12.7 (1/2), or 15.9 (5/8)

Stroking Time

Dependent of actuator size, rotation, spring rate, initial spring compression, supply pressure, and size

of supply piping. If stroking time is critical, consult your Emerson sales office.

Diaphragm Casing Displacement

Clearance Volume⁽³⁾: 623 cm³ (38 cubic inches)

Casing Volume⁽⁴⁾

90 Degree Rotation: 2390 cm³ (146 cubic inches)

60 Degree Rotation: 1890 cm³ (115 cubic inches)

Material Temperature Capabilities⁽¹⁾

NBR (nitrile) Diaphragm or O-rings⁽⁵⁾:

-40 to 82°C (-40 to 180°F)

VMQ (silicone) Diaphragm:

-40 to 149°C (-40 to 300°F)

POM (polyoxymethylene) Push Rods and Guides (used with lever-operated switches):

-40 to 82°C⁽⁶⁾ (-40 to 180°F)

Travel Indication

Graduated disk and pointer

Pressure Connections

Standard: 1/4 NPT internal

Optional: ■ 1/2 or ■ 3/4 NPT internal

Mounting Positions

See figure 2

Approximate Weights

1051: 20 kg (45 pounds)

1052: 21 kg (46 pounds)

1. The pressure/temperature limits in this manual and any applicable standard or code limitation for valve should not be exceeded.

2. Use this value to determine the maximum torque output allowed.

3. Volume when the diaphragm is in the up position.

4. Includes clearance volume.

5. NBR (nitrile) O-rings are used in the optional top-mounted handwheel and in the optional up travel stop assembly.

6. For higher temperature ratings, contact your Emerson sales office.

7. This maximum casing pressure is not to be used for normal operating pressure. Its purpose is to allow for typical regulator supply settings and/or relief valve tolerances.

Do not install, operate, or maintain a 1051 or 1052 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

1051 and 1052 Size 33 spring-and-diaphragm actuators are used on rotary-shaft valve bodies for throttling or on-off applications. The 1051 may be used for on-off service without a positioner or for throttling service with a positioner. The 1052 uses an adjustable spring seat to control spring compression. It may be used for on-off service without a positioner, or it may be used for throttling service with or without a positioner, depending on service conditions.

A top-mounted handwheel may be mounted for infrequent service as a manual override. A manual actuator is recommended for routine and repeated manual operation. Externally adjustable travel stops are used to limit the degree of rotation at both ends of the actuator stroke. Provisions are included for integral mounting of optional magnetic proximity switches. Lever-operated, mechanical switches are also available.

The lever for the 1051 and 1052 size 33 actuator is supported by bushings. The lever may be changed to accommodate valve bodies with different size valve shafts and different mounting adaptations. Levers and accessories are available for mounting valve bodies and equipment with the following mounting adaptations:

F and G mounting adaptations (figures 9 and 10) are for use with Fisher splined-shaft rotary valve bodies with 12.7, 15.9, and 19.1 mm (1/2, 5/8, and 3/4 inch) valve shaft diameters. A stub shaft is available for installation on the end of the lever opposite the valve body for use as a wrench-operated extension (for emergency override) or as a means of connecting a manual actuator (see figure 14).

H mounting (figure 11) is for use with non-Fisher products and user-provided mounting brackets and shaft couplings. It includes a mounting surface with threaded holes for attaching the user-provided mounting bracket. A 22.2 mm (7/8 inch) stub shaft with flats is pinned to the lever and is used to couple the actuator to the operated equipment. A second stub shaft may be installed on the opposite end of the lever for use as a wrench-operated extension (for emergency override) or as a means for connecting a manual actuator (see figure 14). Stub shafts are available in standard and reverse constructions (see figure 12) to provide proper operation with the mounting position and actuator action desired (see figure 2).

J mounting (figure 13) permits use of the actuator with Fisher keyed-shaft valve bodies and other keyed-shaft equipment with 9.5, 12.7, and 15.9 mm (3/8, 1/2, and 5/8 inch) shaft diameters. A stub shaft is pinned to the lever and a valve shaft coupling is pinned to the stub shaft. The coupling has multiple keyways (see figure 4) to accommodate mounting in the desired position. A second stub shaft may be installed on the opposite end of the lever for use as a wrench-operated extension (for emergency override) or as a means for connecting a manual actuator (see figure 14).

Table 2. Bolting Torque Requirements⁽¹⁾

DESCRIPTION KEY NUMBER	BOLT SIZE	TORQUE	
		N•m	Lbf•ft
Diaphragm Casing 5	3/8-24	27	20
Travel Stop 8	7/16-14	27	20
Diaphragm to rod 9	3/8-24	54	40
Rod end to lever 18	3/8-16	54	40
Housing to yoke 23	5/16-18	41	30
Housing to cover 34	5/16-18	41	30
Yoke to valve 71	3/8-16	(See appropriate valve instruction manual)	
Clamped lever 28	3/8-16	54	40
Switch Nut 78	3/8-16	27	20

1. Exceeding any torque requirements could damage the actuator and impair safe operation.

Specifications

Specifications are shown in table 1 for 1051 and 1052 size 33 actuators. Some specifications for a given actuator as it originally comes from the factory are stamped on a metal nameplate attached to the actuator.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

1051 and 1052 Size 33 Actuators

June 2023

Instruction Manual

D101322X012

MOUNTING	ACTION(1)	VALVE SERIES OR DESIGN				VALVE SERIES OR DESIGN		
		BALL/PLUG ROTATION TO CLOSE	V250	V150, V200 & V300	CV500 V500	DISK/BALL ROTATION TO CLOSE	V250	8510B, 8532, 8560 & 9500
Right-Hand	PDTC	CCW	A	A	A	CW	NA	B
	PDTO	CCW	B	B	B	CW	NA	A
Left-Hand	PDTC	CCW	NA	D	D	CW	C	C
	PDTO	CCW	NA	C	C	CW	D	D
Left-Hand (Optional)(2)	PDTC	CW	NA	C	NA	NA	NA	NA
	PDTO	CW	NA	D	NA	NA	NA	NA

1. PDTC—Push-down-to-close, and PDTO—Push-down-to-open.
2. A left hand ball will be required for the NPS 3 through 12 Series B and the NPS 14 to 20, with or without attenuator.

Figure 2. Mounting Styles and Positions for Fisher 1051 and 1052 Actuators

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations.

To avoid personal injury or property damage caused by bursting of pressure retaining parts, do not apply pressure exceeding the Maximum Diaphragm Casing Pressure limit given in table 1 or on the nameplate. Use pressure limiting or pressure relieving devices to prevent the casing pressure from exceeding the maximum diaphragm casing pressure.

Check with your process or safety engineer for any other hazards that may be present from exposure to process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

NOTICE

To avoid parts damage, do not apply pressure that exceeds the Maximum Diaphragm Sizing Pressure (table 1) or produces a torque greater than the Maximum Allowable Valve Shaft Torque (see Catalog 14). Use pressure-limiting or pressure-relieving devices to prevent the diaphragm casing pressure from exceeding these limits.

The actuator, as it comes from the factory, is normally mounted on a valve body. Follow the procedures given in the valve instruction manual when installing the control valve in the pipeline.

If a positioner is ordered with the actuator, the pressure connection to the actuator is normally made at the factory. If it is necessary to make this connection, run either 1/4 inch pipe or 3/8 inch tubing (for standard diaphragm case fittings) between the pressure connection and the instrument. Keep the length of tubing or pipe as short as possible to avoid transmission lag in the control signal.

When the control valve is completely installed and connected to the controlling instrument, check to make sure that the action is correct (air-to-open or air-to-close) and that the controlling instrument is properly configured for the desired action. For successful operation, the diaphragm rod, lever, and valve shaft must move freely in response to changes in the loading pressure on the diaphragm.

Actuator Mounting and Changing Actuator Mounting

Use the following steps to mount the actuator or to change actuator mounting style or position.

F and G Mounting Adaptations

Unless otherwise specified, key numbers referenced in the following procedures are shown in figure 9 for the 1051 actuator and in figure 10 for the 1052 actuator.

1. Proceed as appropriate:

If the Actuator is mounted on a valve body and it is necessary to change mounting style or position, the actuator must first be separated from the valve body. Proceed to the Disassembly portion of the Changing or Replacing Actuator Lever procedure, observe all warnings, perform steps 1 through 6, and return to step 2 which follows.

If the Actuator is not mounted on a valve body, proceed to the Disassembly portion of the Changing or Replacing Actuator Lever procedure, perform steps 2 through 5, and return to step 2 which follows.

2. Refer to figure 2 for available mounting styles and positions. When mounting on a Vee-Ball™ V150, V200 or V300 valve, check the valve manual to determine if it is Series B. The actuator is normally positioned vertically with the valve in a horizontal pipeline.
3. Determine whether the actuator mounting yoke (key 22) will be mounted on the housing cover assembly (key 33) side or on the actuator housing boss side of the actuator. If the desired mounting position and style require moving the mounting yoke and travel indicator (key 35) to opposite sides of the actuator, remove the machine screws (key 38), the travel indicator pointer (key 37), the machine screws, and the travel indicator scale (key 35). Remove the cap screws (key 23) and the mounting yoke. Install the mounting yoke in the desired position (on the housing cover assembly or on the actuator housing boss). See table 2 for recommended torque for the mounting cap screws. Install the travel indicator components on the opposite side of the actuator. See figure 14 for travel indicator components used with wrench-operated extensions and manual actuators.

4. Before sliding the valve shaft into the lever, position the valve ball or disk as follows:

For push-down-to-close action, the valve ball or disk should be in the fully open position.

For push-down-to-open action, the valve ball or disk should be in the fully closed position (see the valve body instruction manual).

5. Make sure that the index markings on the valve shaft are properly aligned with the markings on the lever and slide the valve shaft into the lever. Install the valve mounting cap screws, washers, and nuts and tighten to the torque value given in the appropriate valve body instruction manual.
6. Ensure all end play in the valve shaft is removed by pulling the valve shaft toward the actuator as much as possible. Make sure the actuator rod is perpendicular to the valve shaft. Refer to the valve instruction manual for specific end play considerations.

Figure 3. Travel Stops and Switch Positions on the Fisher 1051 and 1052 Size 33 Actuator

W4738

7. Tighten the socket head cap screw which compresses the splined lever connection to the valve shaft (see table 2).

NOTICE

When adjusting the travel stop for the closed position of the valve ball or disk, refer to the appropriate valve instruction manual for detailed procedures. Undertravel or overtravel at the closed position may result in poor valve performance and/or damage to the equipment.

8. Adjust the up travel stop (see figure 3) so that the valve ball or disk is in the desired position.

⚠ WARNING

To avoid personal injury and equipment damage from moving parts, keep fingers and tools clear while stroking the actuator with the cover removed.

9. Stroke the actuator and adjust the down travel stop so that the valve ball or disk is in the desired position.
10. Make sure that the travel indicator pointer matches the ball or disk position. Remove and install in the proper position if necessary.
11. Install the cover plate or switch mounting plate (key 59) with cap screws (key 60).
12. Refer to the table of contents for accessory installation procedures.

H Mounting Adaptation

Unless otherwise specified, key numbers referenced in the following procedures are shown in figure 9 for the 1051 actuator and in figure 10 for the 1052 actuator. Unique parts used for the H mounting adaptation are shown in figure 11 for single stub shaft construction and in figure 14 for dual stub shaft construction.

1. To change mounting style or position, the actuator must be separated from the valve body (or other operated equipment). Remove the cap screws used to attach the actuator to the valve body (or other operated equipment) and remove the actuator.
2. Determine the desired mounting position. Note that stub shafts are available in standard and reverse constructions so that proper alignment with the operated equipment can be achieved (see figure 12). Refer to figure 2 for available mounting styles and positions.
3. If it is necessary to install or change stub shaft(s), the actuator lever (key 27) must be removed. Perform all applicable operations in the Disassembly portion of the Changing or Replacing Actuator Lever procedure. Install the stub shafts for the construction desired (refer to figures 11 and 14) and reassemble the actuator.
4. Determine whether the operated equipment will be mounted on the housing cover assembly (key 33) side or on the actuator housing boss side of the actuator. Depending on the desired mounting style and position, it may be necessary to move the operated equipment and travel indicator components to opposite sides of the actuator. If so, remove the travel indicator components, the operated equipment, and the mounting bracket if used. Install the operated equipment or mounting bracket in the desired position (on the housing cover assembly or on the actuator housing boss). See table 2 for recommended torque for the mounting cap screws. Install the travel indicator components on the side of the actuator opposite the operated equipment. Refer to figure 14 for travel indicator components used with wrench-operated extensions and manual actuators.

5. Before coupling the operated equipment to the actuator stub shaft, position the equipment as follows:

For push-down-to-activate (open) action, the equipment should be in the fully deactivated (closed) position.

For push-down-to-deactivate (close) action, the equipment should be in the fully activated (open) position.

6. Install the required shaft coupling and the operated equipment.

NOTICE

When adjusting the travel stops to limit rotation, be certain that the rotation produced does not exceed the safe limit of the operated equipment. Undertravel or overtravel may result in poor performance and/or damage to the equipment.

7. Adjust the up travel stop (see figure 3) so that the operated equipment is in the desired position.

⚠ WARNING

To avoid personal injury and equipment damage from moving parts, keep fingers and tools clear while stroking the actuator with the cover removed.

8. Stroke the actuator and adjust the down travel stop so that the operated equipment is in the desired position.
9. Make sure that the travel indicator pointer matches the ball or disk position. Remove and install in the proper position if necessary.
10. Refer to the table of contents for accessory installation procedures.

J Mounting Adaptation

Unless otherwise specified, key numbers referenced in the following procedures are shown in figure 9 for the 1051 actuator and in figure 10 for the 1052 actuator. Unique parts used for the J mounting adaptation are shown in figure 13 for single stub shaft construction and in figure 14 for dual stub shaft construction.

1. If the actuator is mounted on a valve body and it is necessary to change mounting style or position, the actuator must be separated from the valve body. Proceed to the disassembly portion of the Changing or Replacing Actuator Lever procedure, observe all warnings, perform steps 1 through 6, and return to step 2 which follows.
2. Refer to figure 2 for available mounting styles and positions. The actuator is normally mounted vertically on a valve body that is installed in a horizontal pipeline.
3. If it is necessary to install or change stub shaft(s), the actuator lever (key 27) must be removed. Perform all applicable operations in the Disassembly portion of the Changing or Replacing Actuator Lever procedure. Install the stub shafts for the construction desired as shown in figure 13 and reassemble the actuator.
4. Determine whether the actuator mounting yoke (key 22) will be mounted on the housing cover assembly (key 33) or on the actuator housing boss. If the desired mounting position and style requires moving the mounting yoke and travel indicator components to opposite sides of the actuator, remove the travel indicator components, the valve shaft coupling (key 80 for 1051, or key 90 for 1052), cap screws (key 23), and the mounting yoke. Install the mounting yoke in the desired position (on the housing cover assembly or on the actuator housing boss). See table 2 for recommended torque for the mounting cap screws. Install the valve shaft coupling on the actuator stub shaft.

Install the travel indicator components on the opposite side of the actuator. See figure 14 for travel indicator components used with wrench-operated extensions and manual actuators.

5. Before coupling the valve to the actuator, position the valve ball or disk as follows:

For push-down-to-close action, the valve ball or disk should be in the fully open position.

For push-down-to-open action, the valve ball or disk should be in the fully closed position (see the valve body instruction manual).

6. The valve shaft coupling (see figure 4) has two keyways lettered A and B (the letters C and D on the coupling are not used and may be disregarded). Align the appropriate keyway with the keyway in shaft of the operated equipment.

When used with a Fisher butterfly valve body, refer to the table and illustration in figure 4 for proper orientation of the coupling and valve shaft. Install the woodruff key (key 81 for 1051, key 91 for 1052) in the valve shaft keyseat, lubricate the inside of the coupling, and slide the valve shaft into the coupling.

7. Install the valve mounting cap screws, washers, and nuts and tighten to the torque value given in the appropriate valve body instruction manual.

NOTICE

When adjusting the travel stop for the closed position of the valve ball or disk, refer to the appropriate valve body instruction manual for detailed procedures. Undertravel or overtravel at the closed position may result in poor valve performance and/or damage to the equipment.

8. Adjust the up travel stop so that the valve ball or disk is in the desired position.

⚠ WARNING

To avoid personal injury and equipment damage from moving parts, keep fingers and tools clear while stroking the actuator with the cover removed.

9. Stroke the actuator and adjust the down travel stop so that the valve ball or disk is in the desired position.
10. Make sure that the travel indicator pointer matches the ball or disk position. Remove and install in the proper position if necessary.
11. Refer to the table of contents for accessory installation procedures.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

1051 and 1052 Size 33 Actuators

June 2023

Instruction Manual

D101322X012

DESIRED ACTUATOR ACTION	DESIRED SHAFT ROTATION, DEGREES	ACTUATOR MOUNTING POSITION	COUPLING KEYWAY TO USE ⁽³⁾	VALVE SHAFT KEYWAY TO USE FOR FISHTAIL™ DISK VALVE BODIES ⁽¹⁾ (SEE FIGURE 2)			
				Clockwise to Close Valve Action ⁽²⁾		Counterclockwise to Close Valve Action ⁽²⁾	
				Flow Left to Right ⁽²⁾	Flow Right to Left ⁽²⁾	Flow Left to Right ⁽²⁾	Flow Right to Left ⁽²⁾
Push Down to Open (PDTO)	60 or 90	1	B	Nose	Tail	Tail	Nose
		2	A	Tail	Nose	Nose	Tail
		3	B	Tail	Nose	Nose	Tail
		4	A	Nose	Tail	Tail	Nose
Push Down to Close (PDTC)	60 ⁽³⁾ or 90	1	A	Tail	Nose	Tail	Nose
		2	B	Tail	Nose	Tail	Nose
		3	A	Nose	Tail	Nose	Tail
		4	B	Nose	Tail	Nose	Tail

1. For conventional disk valve bodies, use either valve shaft keyway.
2. When viewed from actuator side of valve body.
3. For 60-degree rotation with PDTC action, the coupling and actuator output shaft assembly will offset 30 degrees clockwise (for actuator housing construction style B), or counterclockwise (for actuator housing construction style A) in the lever when viewed from the splined end of the actuator shaft. 30 degrees is one spline tooth for 9.5, 12.7, and 15.9 mm (3/8, 1/2, and 5/8 inch) valve shafts and two spline teeth for 19.1 mm (3/4 inch) valve shafts.

FOR USE WITH J MOUNTING ADAPTATION.

Figure 5. Spring Adjustment

1052 Spring Compression Adjustment

Initial Compression

Key numbers referred to in this procedure are shown in figure 10 unless otherwise specified.

The 1052 nameplate specifies an initial set adjusted into the actuator spring. Initial set is the casing pressure at which the diaphragm (key 3) and diaphragm rod (key 10) begin to move away from the stop in the upper diaphragm case (key 1) when the actuator is disengaged from the control valve body or other operated equipment. The initial set was determined from the service conditions specified when the actuator was ordered, so that when the actuator and valve are in service, the valve ball or disk seats properly and full travel is obtained with the supply pressure specified on the order and shown on the nameplate.

Before adjusting spring tension to change initial set, the valve body or other operated equipment must be removed or otherwise disengaged from the actuator. Refer to the applicable steps given under the appropriate mounting adaptation in the Actuator Mounting and Changing Actuator Mounting procedure.

To gain access to the spring adjusting screw, either the spring adjuster cover (key 117) or the switch mounting plate (key 59) must be removed. If externally mounted switches are used, remove them as an assembly by removing the cap screws (key 75, figure 16) and the switch mounting plate (key 1, figure 16). In order to gain access to the cap screws, it may be necessary to loosen the hex nuts (key 77, figure 16) and slide the switches away from the actuator housing.

Note that the lower part of the spring adjusting screw (key 74) is notched so that it can be rotated with a screwdriver or other flat-bladed tool. To decrease spring compression, rotate the spring adjusting screw to the right (see figure 5). To increase spring compression, rotate the spring adjusting screw to the left (clockwise when viewed from above). Adjust the spring so that the diaphragm rod just starts to travel at the initial set pressure specified on the nameplate. When the desired initial set has been achieved, install the spring adjuster cover or switch mounting plate.

Table 3. Spring for Fisher 1052 Actuator⁽¹⁾

CASING PRESSURE		INITIAL SPRING COMPRESSION					
		60 Degree Rotation		90 Degree Rotation			
Bar	Psig	Push-down-to-open		Push-down-to-open		Push-down-to-close	
		Bar	Psig	Bar	Psig	Bar	Psig
0-1.2	0-18	0.3	3.9	0.2	2.7	0.2	2.7
		0.4	5.4	0.3	3.7	0.2	3
		0.4	6.1	0.3	4.9	0.2	3
0-2.3	0-33	0.3	3.9	---	---	0.2	2.7
		0.4	5.4	0.3	3.7	0.3	3.7
		0.5	7.1	0.3	4.9	0.3	4.9
		0.7	9.7	0.4	6.3	0.2	3
0-2.8	0-40	0.3	3.9	---	---	0.2	2.7

0.2-2.1	3-30	---	---	---	---	0.3	3.7
		---	---	0.3	4.9	0.3	4.9
		---	---	0.4	6.3	0.2	3

1. For more detailed information concerning proper spring selection to obtain the torque required, consult your [Emerson sales office](#).

Stroking Range

Key numbers referred to in this procedure are shown in figure 10 unless otherwise specified.

If, under operating conditions, the desired stroking range cannot be achieved with the casing pressure used, it may be possible to shift the stroking range by making a spring adjustment to change the initial spring compression. A spring adjustment shifts the casing pressure span and equally increases (or decreases) the casing pressure at which the actuator begins to stroke and the pressure at which the actuator reaches full travel.

To gain access to the spring adjusting screw, either the spring adjuster cover (key 117) or the switch mounting plate (key 59) must be removed. If externally mounted switches are used, remove them as an assembly by removing the cap screws (key 75, figure 16) and the switch mounting plate (key 1, figure 16). In order to gain access to the cap screws, it may be necessary to loosen the hex nuts (key 77, figure 16) and slide the switches away from the actuator housing.

Note that the lower part of the spring adjusting screw (key 74) is notched so that it can be rotated with a screwdriver or other flat bladed tool. To shift the casing pressure span downward, rotate the spring adjusting screw to the right (see figure 5). To shift the casing pressure span upward, rotate the spring adjusting screw to the left. When the desired stroking range has been achieved, replace the spring adjuster cover or the switch mounting plate.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions. Instructions are given below for disassembly and assembly of parts. Key numbers referenced in the following steps are shown in figure 9 for the 1051 actuator and in figure 10 for the 1052, except as listed below or otherwise specified in the procedures.

Mounting Adaptations

F and G Adaptations

The procedures given in this instruction manual apply directly to F and G mounting adaptations. Refer to figures 9 and 10.

H Mounting Adaptations

Whenever the procedures require separating the actuator from the operated equipment, it may be necessary to remove brackets, couplings, and stub shafts before proceeding. Refer to figure 11 for parts used with the H mounting adaptation.

J Mounting Adaptations

Whenever the procedures require separating the actuator from the valve body, it may be necessary to remove couplings and keyways. Refer to figure 13 for parts used with the J mounting adaptation.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings.
- Check with your process or safety engineer for any hazards that may be present from exposure to process media.

Replacing Diaphragm

Disassembly

1. Bypass the control valve. Relieve all loading pressure, and remove the tubing or pipe from the upper diaphragm case (key 1).
2. Observe the position of the travel indicator pointer (key 37) and mark its position on the travel indicator scale (key 35).

⚠ WARNING

Failure to control spring tension against the upper diaphragm case as outlined in the following step could result in sudden spring decompression causing bodily injury or equipment damage. Control spring tension by following step 3 closely.

3. Loosen the hex jam nut (key 84 for 1051, or key 86 for 1052) on the up travel stop. This stop is nearest to the positioner or positioner cover (key 39; also see figure 3). Screw the travel stop in (turn it clockwise) until it can be verified that all spring tension has been removed from the diaphragm stop in the upper diaphragm case, i.e. when any movement of the travel indicator pointer is observed, all spring tension against the upper diaphragm case stop has been removed. Do not rotate the travel stop past this position as additional compression of the spring is not necessary or desirable.
4. Carefully remove all cap screws and hex nuts (keys 5 and 6) from the diaphragm case.
5. Remove the diaphragm case and the diaphragm (key 3).
6. Inspect the diaphragm plate (key 4). If the diaphragm plate is damaged or if further disassembly of the actuator is required, proceed to the Diaphragm Plate, Diaphragm Rod, Spring, and Spring Seat procedure.
7. Inspect the diaphragm and replace if necessary.

Assembly

1. Place the diaphragm (key 3) on the diaphragm plate (key 4), making certain that it is properly centered.
2. Make sure that the up travel stop (see figure 3) is screwed in sufficiently to eliminate interference of the diaphragm plate (key 4) with the upper diaphragm case.
3. Observe the correct position of the loading connection fitting and install the upper diaphragm case (key 1). Replace the cap screws and nuts (keys 5 and 6) which secure the upper diaphragm case to the actuator housing. Tighten the nuts in an alternating fashion (see table 2).

NOTICE

When adjusting the travel stop for the closed position of the valve ball or disk, refer to the appropriate valve body instruction manual for detailed procedures. Undertravel or overtravel of many valve types may result in poor valve performance and/or damage to the equipment.

4. Adjust the up travel stop (see figure 3). If the upper travel stop establishes the closed position of the valve ball or disk, refer to the valve body instruction manual and follow the procedures given for properly establishing the closed position. Proceed as appropriate:

For F, G, and J mounting adaptations, perform operations beginning with step 8 under the appropriate mounting adaptation section of the Actuator Mounting and Changing Actuator Mounting procedure.

For H mounting adaptations, perform operations beginning with step 7 under the appropriate mounting adaptation section of the Actuator Mounting and Changing Actuator Mounting procedure.

5. Return the travel indicator pointer to its original position as previously marked on the travel indicator scale.
6. Install the inlet piping to the upper diaphragm case.

Replacing Diaphragm Plate, Diaphragm Rod, Spring, and Spring Set

Disassembly

1. Perform steps 1 through 6 of the Disassembly portion of the Replacing Diaphragm procedure above.

For 1052 Actuators Only

- a. Before removing the diaphragm plate, spring compression must be relieved. Proceed as appropriate to gain access to the spring adjusting screw:

- Without lever-operated switches, remove the cap screws (key 21) and the spring adjuster cover (key 117).
- With lever-operated switches, remove the switches as an assembly by removing the cap screws (key 75, figure 16) and the switch mounting plate (key 1, figure 16). In order to gain access to the cap screws, it may be necessary to loosen the hex nuts (key 77, figure 16) and slide the switches away from the actuator housing.

⚠ WARNING

To avoid personal injury from precompressed spring force suddenly thrusting parts away from the actuator, spring compression must first be relieved by rotating the spring adjusting screw until the spring seat is bottomed against the spring adjuster. Closely follow the instructions below.

- b. To relieve spring compression, insert a screwdriver into the notches on the spring adjusting screw and rotate the spring adjusting screw to the right (counter-clockwise when viewed from the top of the actuator) until the spring seat (key 13) is bottomed against the spring adjuster.
2. For 1051 and 1052 Actuators, using a 5/16 inch hex wrench, unscrew and remove the socket head cap screw (key 9) which secures the diaphragm plate (key 4) to the diaphragm rod (key 10). Remove the diaphragm plate and the upper thrust washer (key 83 for 1051, or key 72 for 1052).
 3. For the 1051, remove the spring (key 11) and spring seat (key 14).
For the 1052, remove the spring (key 11), spring seat with adjusting screw (keys 74 and 14), and lower thrust washer (key 72).

Note

At this stage of disassembly, it may be determined that further disassembly is not necessary. If separation of the diaphragm rod from the lever is not warranted, proceed to the Assembly portion of this procedure.

4. To gain access to the cap screw (key 18) which secures the diaphragm rod to the lever, the housing cover assembly (key 33) must be removed. Before the housing cover assembly can be removed, one of the following procedures must be performed. Proceed as appropriate:

For actuators with valve bodies mounted on the housing cover assembly (key 33) side of the actuator, the actuator must be separated from the valve body to provide access to the cap screw (key 18). Proceed to the Disassembly portion of the Changing or Replacing Actuator Lever procedure and perform steps 2 through 6.

For actuators with valve bodies mounted on the actuator housing boss side of the actuator, remove the travel indicator pointer (key 37).

5. Remove the cap screws and washers (keys 34 and 63) and the housing cover assembly (key 33).
6. Remove the outer switch cam, if used, by removing the two hex head machine screws, spacers, and retaining washers (keys 119, 132, and 144, figures 15 and 16). Note that the retaining washers help to keep all parts together as an assembly.
7. Remove the cap screw (key 18) that secures the actuator lever (key 27) to the diaphragm rod. Remove the diaphragm rod.
8. Inspect all parts and replace if necessary.
9. If total disassembly of the actuator is required, or if the actuator will be assembled for use with a valve body with a different valve shaft diameter, proceed to the Changing or Replacing Actuator Lever procedure.

SPRING NO.	DIMENSION A	
	mm	Inches
10B1522	42.7	1.68
10B1523	42.7	1.68
10B1524	42.7	1.68
10B1525	36.6	1.44

Figure 6. Spring Seat Pre-Set Dimensions for the Fisher 1052 Size 33 Actuator

Assembly

For the 1052 Only

- Lubricate the threads of the spring adjusting screw (key 74) with lithium grease. Also lubricate the bottom portion of the spring adjusting screw which contacts the lower thrust washer (key 72).
- Screw the spring adjusting screw onto the spring seat (key 14) to minimize spring seat adjustment after assembly, refer to figure 6 and pre-set the spring adjusting screw to the appropriate dimension.
- Place the lower thrust washer into the lower spring barrel area.

For 1051 and 1052

- Lubricate the threads of the socket head cap screw (key 9) with lithium grease. Also lubricate the bottom surface of the diaphragm plate which contacts the upper thrust washer (key 83 for 1051, or key 72 for 1052).
- Insert the socket head cap screw through the diaphragm plate (key 4) and into the diaphragm rod (key 10). Tighten the cap screw four or five turns.
- Install the spring seat (with spring adjusting screw for the 1052 actuator), spring, and upper thrust washer.
- Insert the diaphragm plate/diaphragm rod assembly into the spring barrel. Make sure that the notch in the diaphragm rod is oriented according to the view shown in figures 9 and 10, i.e. the notch in the diaphragm rod must face the positioner or positioner cover plate (key 39).
- Rotate the lever so that it straddles the spherical bearing in the diaphragm rod. It may be necessary to exert lateral pressure on the diaphragm rod to achieve alignment of the rod with the lever. Install the cap screw (key 18) (see table 2). Use the up travel stop (see figure 3) to keep the lever from rotating during tightening.
- If the actuator uses an outer switch cam, install the outer cam (key 170, figures 15 and 16) using the two hex head machine screws, spacers, and retaining washers (keys 119, 132, and 144). Note that the retaining washers help to keep all parts together as an assembly to ease installation. Make sure that the cam is mounted on the lever according to the orientation shown in figure 7.

Figure 7. Orientation of Switch and Positioner Cams on the Lever of the Fisher 1051 and 1052 Size 33 Actuator

7. Install the housing cover assembly (key 33) with cap screws and washers (keys 34 and 63).
 8. Tighten the socket head cap screw (key 9) with a 5/16 hex wrench until the diaphragm plate is fully seated against the diaphragm rod. Tighten the cap screw to the torque value in table 2.
 9. Perform steps 1 through 5 of the Assembly portion of the Replacing Diaphragm procedure.
 10. For 1052 actuators, refer to the 1052 Spring Compression Adjustment procedure and adjust the spring for the desired initial set.
 11. Install the cover plate or switch mounting plate (key 59) with cap screws (key 60). If switches are used, observe the marks made during removal of the cover plate.
 12. Install the spring adjuster cover (key 117) or the switch mounting plate (key 1, figure 16) with the appropriate cap screws.
 13. Install the travel indicator (key 37) if removed.
 14. If the actuator was removed from the valve body, refer to the appropriate section in the Actuator Mounting and Changing Actuator Mounting procedure and proceed as follows:
- For F and G mounting adaptations, perform all applicable steps beginning with step 3.
- For H and J mounting adaptations, perform all applicable steps beginning with step 4.

Changing or Replacing Actuator Lever

Note

The lever and associated parts may be removed as an independent procedure without disassembling the upper diaphragm casing or spring barrel components. Or, the lever may be removed after performing the operations given in the Replacing Diaphragm procedure and in the Diaphragm Plate, Diaphragm Rod, Spring, and Spring Seat procedure.

Disassembly

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings.
- Check with your process or safety engineer for any other hazards that may be present from exposure to process media.

1. Isolate the valve body from the process. Release process pressure and vent all actuator pressure.
2. If externally mounted switches are used, remove them as an assembly by removing the cap screws (key 75, figure 16) and the switch mounting plate (key 1, figure 16). In order to gain access to the cap screws, it may be necessary to loosen the hex nuts (key 77, figure 16) and slide the switches away from the actuator housing.
3. If switches are used, mark the position of the switch mounting plate (key 59) on the actuator housing so it may be returned to the exact same position.
4. Remove the cap screws (key 60) and the cover plate or switch mounting plate (key 59). If switches are used, leave the push rod assemblies (keys 169 and 170, figure 16) or the proximity switch assemblies (key 7, figure 15) undisturbed.
5. Using a 5/16 inch hex wrench, loosen the socket head cap screw (key 28) which compresses the splined lever connection around the valve shaft.
6. Separate the actuator from the valve body by removing the cap screws and washers which secure the valve to the mounting yoke (key 22). For some constructions of H and J mounting adaptations, it may be necessary to remove other mounting and coupling parts.
7. If the valve body (or other operated equipment) is mounted on the housing cover (key 33) side of the actuator, remove the mounting yoke and travel indicator pointer.
8. Remove the cap screws and washers (keys 34 and 63) and the housing cover (key 33).
9. If the actuator is equipped with a positioner, remove the positioner cam (see figure 7) by removing the two hex head machine screws which secure the cam to the lever.
10. If the actuator is equipped with cam-operated switches, remove the outer cam (see figure 7) with the two hex head machine screws, spacers, and retaining washers (keys 119, 132, and 144, figures 15 and 16). Note that the retaining washers help to keep all parts together as an assembly.

⚠ WARNING

Failure to relieve spring tension on the diaphragm rod to lever connection before removing the cap screw (key 18) may result in personal injury and equipment damage from sudden and forceful movement of the diaphragm rod. Relieve spring tension by performing the operations described in the next step.

11. Relieve all spring loading on the diaphragm rod (key 10) to lever (key 27) connection by backing out (turning counter-clockwise) the up position travel stop (see figure 3). When the travel stop is no longer in direct contact with the lever (key 27), it can be determined that all spring compression is being contained by the stop in the upper diaphragm case (key 1).
12. Remove the cap screw (key 18) which secures the diaphragm rod (key 10) to the lever (key 27). Disconnect the lever from the diaphragm rod by rotating the lever away from the diaphragm rod.
13. Remove and inspect the lever. If the lever is worn or damaged, or if the actuator will be mounted to a valve body requiring a different size lever, replace the lever.
14. Inspect the bushings (key 31). If bushings are excessively worn or damaged, remove them with a press. Press in new bushings so that they are flush with the interior surfaces of the actuator housing boss and housing cover assembly.

Assembly

1. Refer to figure 7 for the correct orientation of the inner switch cam (if used); be sure that it is attached to the lever in the proper orientation.
2. Refer to figure 7 for the correct orientation of the lever during assembly. Insert the lever into the bushing in the actuator housing boss.
3. If the diaphragm rod has been removed, perform all operations through step 3 of the Assembly portion of the Diaphragm Plate, Diaphragm Rod, Spring and Spring Seat procedure.
4. Rotate the lever so that it straddles the spherical bearing in the diaphragm rod. It may be necessary to exert lateral pressure on the diaphragm rod to achieve alignment of the rod with the lever. Install the cap screw (key 18) and tighten to the torque value in table 2.
5. If an outer switch cam is used, install the cam using the two machine screws, spacers, and retaining washers. Note that the retaining washers help to keep all parts together as an assembly. Observe the orientation shown in figure 7.
6. If a positioner is used, install the positioner cam with machine screws. Be sure to observe the orientation shown in figure 7 and follow all procedures given in the positioner instruction manual.
7. Install the housing cover assembly (key 33).
8. If the diaphragm plate has been removed, tighten the socket head cap screw (key 9) with a 5/16 hex wrench until the diaphragm plate is fully seated against the diaphragm rod. Tighten the cap screw to the torque value in table 2.
9. If the upper diaphragm case has been removed, perform all applicable steps in the Assembly portion of the Replacing Diaphragm procedure.
10. Refer to the Actuator Mounting and Changing Actuator Mounting procedure and proceed as follows:
 - For F and G mounting adaptations, start with step 3.
 - For H and J mounting adaptations, start with step 4.
11. For 1052 actuators only, refer to the 1052 Spring Compression Adjustment procedure and adjust the spring for the desired initial set.

Proximity Switches, Lever Operated Switches, and Positioner

The proximity switches (see figure 15), lever operated switches (see figure 16), and positioner used with 1051 and 1052 size 33 actuator use cams (see figure 7) mounted on the lever to transmit valve ball or disk position feedback to the accessories. These cams must be attached to the lever before accessories can be installed.

Installing the Cam

Key numbers referred to in the following procedures are shown in figure 15 for proximity switch installation and in figure 16 for lever operated switch installation unless otherwise specified. Proceed as appropriate:

For switches which activate at the bottom of the actuator stroke, the inner cam (key 170; also see figure 7) is used. Installation of the inner cam requires removal of the actuator lever (key 27, figures 9 and 10). To remove the lever, refer to the Changing or Replacing Actuator Lever procedure and perform all applicable steps in the Disassembly portion. Install the inner cam with machine screws and retaining washers (keys 117 and 144). Note that the retaining washers help to keep all parts together as an assembly to ease installation. Reassemble the actuator and install the actuator on the valve body.

For switches which activate at the top of the actuator stroke, the outer cam (key 170; also see figure 7) is used. If the valve body or other operated equipment is mounted on the housing cover assembly side of the actuator, it will be necessary to remove the valve body and the mounting yoke. Refer to the Changing or Replacing Actuator Lever procedure and perform all applicable steps in the Disassembly portion. Remove the housing cover assembly (key 33). Install the outer cam with machine screws, spacers, and retaining washers (keys 119, 132, and 144). Note that the retaining washers help to keep all parts together as an assembly to ease installation. Follow the steps in the Installation section to reassemble the actuator and install the actuator on the valve body.

For actuators using a positioner, the positioner cam (see figure 7) must be installed on the lever. If the valve body or other operated equipment is mounted on the housing cover assembly side of the actuator, it will be necessary to remove the valve body and the mounting yoke. Refer to the Changing or Replacing Actuator Lever procedure and perform all applicable steps in the Disassembly portion. Remove the housing cover assembly (key 33). Install the cam on the lever with machine screws in the orientation shown in figure 7 and in the positioner instruction manual. Follow the steps in the Installation section to reassemble the actuator and install the actuator on the valve body.

Installing Proximity Switches

Key numbers referenced in the following procedures are shown in figure 15 unless otherwise specified.

Switches Indicating Bottom of Stroke

1. Apply inlet pressure to the diaphragm case (key 1, figures 9 and 10) until the actuator is at the bottom of its stroke. Make sure that the lever (key 27, figures 9 and 10) is against the down position travel stop (see figure 3).
2. Install one 5/8 inch UNF jam nut (key 78) onto the proximity switch (key 7). Screw the switch assembly into the mounting cover (key 59, figures 9 and 10) so that it is directly over the inner cam (refer to figure 3).
3. Carefully screw the switch into the mounting cover until the electrical contacts close. Maintain a minimum of 0.5 mm (0.02 inch) clearance between the switch and the cam.
4. Lock the switch in place by tightening the locknut (key 78) to the torque value in table 2. When tightening the locknut, be careful not to turn the switch and thereby reduce its clearance with the cam.

Switches Indicating Top of Stroke

1. Make sure that the air supply to the diaphragm case (key 1, figures 9 and 10) is totally vented and the lever (key 27, figures 9 and 10) is against the up position travel stop (see figure 3).
2. Install one 5/8 inch UNF jam nut (key 78) onto the proximity switch (key 7). Screw the switch assembly into the mounting cover (key 59, figures 9 and 10) so that it is directly over the outer cam (refer to figure 3).
3. Carefully screw the switch into the mounting cover until the electrical contacts close. Maintain a minimum of 0.5 mm (0.02 inch) clearance between the switch and the cam.
4. Lock the switch in place by tightening the locknut (key 78) to the torque value in table 2. When tightening the locknut, be careful not to turn the switch and thereby reduce its clearance with the cam.

Installing Lever-Operated Switch

Refer to figure 16 for the key numbers referenced in the following procedures and for proper orientation of switches and switch mounting accessories.

Installing the Push Rod

1. For **Switches Indicating Bottom of Stroke**, apply inlet pressure to the diaphragm case (key 1, figures 9 and 10) until the actuator is at the bottom of its stroke. Make sure that the lever (key 27, figures 9 and 10) is against the down position travel stop (see figure 3).

For **Switches Indicating Top of Stroke**, make sure that the air supply to the diaphragm case (key 1, figures 9 and 10) is totally vented and the lever (key 27, figures 9 and 10) is against the up position travel stop (key 8, figures 9 and 10).

2. For **Switches Indicating Bottom of Stroke**, install one jam nut (key 78) onto the push rod guide (key 169). Refer to figure 3 and screw the push rod guide into the mounting cover (key 59, figures 9 and 10) so that it is directly over the inner cam.

For **Switches Indicating Top of Stroke**, install one jam nut (key 78) onto the push rod guide (key 169). Screw the push rod guide into the mounting cover (key 59, figures 9 and 10) so that it is directly over the outer cam (refer to figure 3).

3. For both kinds of switches, insert the push rod (key 168) into the push rod guide with its head resting against the outer surface of the push rod guide.
4. Screw the push rod guide/push rod assembly in until the push rod contacts the cam (key 170).
5. Hold the push rod tightly against the push rod guide and screw the push rod guide into the mounting cover until a gap of 6.4 to 6.8 mm (0.25 to 0.27 inch) exists between the push rod head and the surface of the push rod guide.
6. Lock the push rod guide in place by tightening the locknut to the torque value in table 2. Be careful not to turn the push rod guide and thereby reduce its clearance with the push rod head.
7. Install the boot (key 163) over the push rod and the push rod guide.

Mounting Lever-Operated Switch and Adjustment

1. If used, remove the cap screws and spring adjuster cover (keys 21 and 85 for 1051, or keys 21 and 117 for 1052).
2. Attach the switch mounting plate (key 1) at this location with cap screws (key 75). Tighten the cap screws to the torque value in table 2.
3. Install the levers onto the switch shafts so that they are parallel to the centerline of the switch when they trip.
4. Insert the round head carriage bolts (key 4) into the switch mounting bracket (key 129). Mount the limit switch onto the bracket using machine screws and nuts (keys 8 and 9). Tighten the machine screws to 2.8 N•m (5 lbf•ft).
5. Attach the switch/mounting bracket assembly to the mounting plate using the nuts and washers (keys 77 and 154).
6. Adjust the switch lever on the shaft so that its roller is in the approximate center of the push rod.
7. With the actuator set at one end of its travel, slide the appropriate switch/bracket assembly toward the actuator until the roller on the switch lever is in contact with the push rod head and the switch contacts close. Stroke the actuator to the opposite end of its travel and repeat the adjustment procedure for the other switch.

Positioner Mounting

1. Before installing the positioner, the positioner cam must be installed on the lever (key 10, figures 9 and 10). Refer to the Installing the Cam procedure.
2. Refer to the positioner instruction manual for setup and calibration procedures.

Top-Mounted Handwheel

Key numbers used in this procedure are shown in figure 17 except where indicated.

The optional top-mounted handwheel can be used as a manual actuator for intermittent service or as an adjustable up travel stop to limit full retraction of the diaphragm rod (key 10, figures 9 and 10).

The handwheel assembly is attached to a special upper diaphragm casing (key 1, figures 9 and 10) with cap screws (key 141). A hex nut (key 137) locks the handwheel in position. For field installation of a handwheel, the special upper diaphragm case must be ordered as well as the handwheel.

Turning the handwheel (key 51) clockwise into the upper casing forces the pusher plate (key 135) against the diaphragm and diaphragm plate (keys 3 and 4) to compress the spring (key 11, figures 9 and 10) and move the diaphragm rod downward. Turning the handwheel counter-clockwise allows the actuator spring to move the diaphragm rod upward. If the valve is push-down-to-close, full opening can be restricted by positioning the handwheel at the desired position. If the valve is push-down-to-open, full closing of the valve ball or disk can be restricted by use of the handwheel.

Instructions are given below for complete disassembly and assembly required for inspection and parts replacement.

Disassembly

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing away from the actuator, relieve spring compression before diaphragm casing bolting is loosened.

1. Remove the upper diaphragm casing (key 1, figures 9 and 10) by following steps 1 through 5 of the disassembly portion of the Replacing Diaphragm procedure.
2. Remove the cotter pin, hex nut, handwheel, and locknut (keys 247, 54, 51, and 137). Unscrew the stem (key 133) out through the actuator end of the handwheel body (key 142).
3. Remove cap screws (key 141), and separate the handwheel assembly from the upper casing.
4. Check the condition of the O-rings (keys 138 and 139); replace them if necessary.
5. If it is necessary to remove the pusher plate or spacer (key 135 or 171), drive out the groove pin (key 140).

Assembly

1. Before assembling, lubricate the thread of the stem (key 133) with anti-seize lubricant (key 244). Lubricate the bearing surfaces of the stem and pusher plate (key 135) with lithium grease (key 241).
2. If the pusher plate or spacer was removed, attach them to the stem and drive in a new groove pin (key 140).
3. With the O-ring (key 138) in place, thread the stem into the handwheel assembly.
4. Attach the handwheel assembly to the upper diaphragm casing (key 1, figures 9 and 10) with cap screws (key 141).
5. Install the locknut, handwheel, hex nut, and cotter pin (keys 137, 51, 54, and 247).
6. Install the diaphragm casing, making certain the warning tag is in place on the casing flange.
7. Tighten the cap screws (key 5, figures 9 and 10) evenly in a crisscross pattern (see table 2).
8. Adjust the initial set as described in the Spring Compression Adjustment procedure.

Locking Mechanism

Installing the Locking Mechanism

⚠ WARNING

To avoid personal injury, perform the steps in the WARNING at the beginning of the Maintenance section to isolate the control valve and actuator.

Figure 8. Fisher 1051 and 1052 Actuator Locking Mechanism

To add the locking mechanism to an existing actuator, purchase the required parts from Emerson Automation Solutions.

1. Remove cap screws, spring adjustor cover, and cover plate (keys 21 and 60, 85 or 117, and 59).
2. Thread jam nut (key 128) all the way onto the threaded bolt portion of the locking device before threading it into the cover (key 59).
3. After the bolt is threaded into the cover, drive the groove pin (key 127) into the threaded bolt. So the locking mechanism will not interfere with rotation of the lever (key 27), rotate the locking mechanism counterclockwise until it is stopped by the groove pin (key 127). Attach the cover to the actuator with cap screws (key 60).
4. Attach mounting plate (key 123) with cap screws (key 21).
5. Be sure the diaphragm rod is retracted fully. This will be the locked position of the valve.
6. Screw the threaded bolt into the cover until it contacts the actuator lever.
7. Rotate the locking device slightly until the hole in the mounting plate (key 123) aligns with a hole in the locking device.
8. Tighten the jam nut against the cover.
9. Insert the padlock (not furnished by Emerson Automation Solutions) to connect the mounting plate with the locking device.

Operating the Locking Mechanism

To Unlock the Actuator

1. Remove the padlock. Loosen the jam nut (key 128), and unscrew the threaded bolt until it is stopped by the groove pin (key 127) in the threaded bolt.

Note

For normal operation of the actuator, the threaded bolt must be unscrewed far enough that the actuator lever will not contact the bolt in normal actuator operation.

- If you are going to leave the bolt threaded into the cover, lock it with the jam nut (key 128) so that it cannot be screwed into the cover and interfere with normal actuator operation.

To Lock the Actuator

- Make sure the actuator diaphragm rod is retracted fully (the locked position of the valve). For a push-down-to-close valve and actuator, the valve will be fully open when locked. For a push-down-to-open valve and actuator, the valve will be fully closed when locked.
- Make sure the jam nut (key 128) is loose. Then, screw the threaded bolt into the cover until it contacts the actuator lever.
- Rotate the threaded bolt until one of the holes in the locking disk (which is welded to the bolt) is in line with the hole in the mounting plate (key 123). Tighten the jam nut against the cover.
- Lock the plate and disk together with a padlock (not furnished by Emerson).

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, refer to the serial number found on the actuator nameplate.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts Kits

Key	Description	Part Number
	Retrofit Kits	
	Kit provides parts to add a top-mounted handwheel.	
	Kit number 1 includes the handwheel assembly only.	
	Kit number 2 includes Kit number 1 and a new Upper Case (key 1) required to mount the handwheel assembly.	
	Kit Number 1	28A1205X082
	Kit Number 2	28A1205X092

Introduction

Scope of Manual

This manual provides installation, adjustment, operation, maintenance, and parts ordering information for Fisher 1051 (sizes 40 and 60) and 1052 (sizes 40, 60, and 70) diaphragm rotary actuators with H and J mounting adaptations (see figures 1 and 2). Also, this instruction manual provides information for the optional top-mounted handwheel, and both the optional up and down travel stops. Instructions for the control valve body, the positioner, accessories, and other sizes or constructions of this actuator are covered in separate manuals.

Table 1. Fisher 1051 and 1052 Actuator Specifications

Operation Direct Acting: Increasing loading pressure extends the diaphragm rod out of the spring barrel Service: 1051: For on-off or throttling service with positioner 1052: For on-off or throttling service with or without a positioner Actuator Sizes 1051: 40, and 60 1052: 40, 60, and 70 Maximum Diaphragm Sizing Pressure⁽²⁾ Size 40: 4.5 bar (65 psig) Size 60: 2.8 bar (40 psig) Size 70: 3.8 bar (55 psig) Maximum Diaphragm Casing Pressure⁽³⁾ Size 40: 5.2 bar (75 psig) Size 60: 3.4 bar (50 psig) Size 70: 4.5 bar (65 psig) Maximum Valve Shaft Rotation 90, 75, or 60 deg with optional stops Torque Limits⁽⁴⁾ Limited by maximum diaphragm sizing pressure or tables 2 and 3, whichever is less	Stroking Time Dependent on actuator size, rotation, spring rate, initial spring compression, and supply pressure. If stroking time is critical, consult your Emerson sales office Material Temperature Capabilities⁽³⁾ Nitrile Diaphragm or O-Rings⁽¹⁾: -40 to 82°C (-40 to 180°F) Silicone Diaphragm: -40 to 149°C (-40 to 300°F) Travel Indication Graduated disk and pointer combination located on actuator end of valve shaft Pressure Connections 1/4 NPT internal Mounting Positions See figure 10 Approximate Weights See table 8 Additional Specifications For casing pressure ranges and for material identification of the parts, see the Parts List
---	---

1. Nitrile O-rings are used in optional top-mounted handwheel, adjustable down travel stop, and adjustable up travel stop assemblies.

2. Use this value to determine the maximum torque output allowed.

3. The pressure / temperature limits in this manual and any applicable standard or code limitation for valve should not be exceeded.

4. Exceeding any torque limits could damage the actuator and impair safe operation.

Do not install, operate, or maintain a 1051 or 1052 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

1051 and 1052 diaphragm rotary actuators are pneumatic spring-return actuators for use with rotary-control valves and other equipment. The 1051 actuator can be used for on-off service, or it can be used for throttling service when equipped with a valve positioner. The 1052 actuator can be used for on-off service, or it can be used for throttling service when equipped with or without a valve positioner. The 1052 actuator spring is adjustable.

The H mounting adaptation permits the actuator to be used with equipment other than Fisher valve bodies. The mounting brackets and couplings for rotary actuation are user-provided. This mounting adaptation includes a flat-surface mounting plate that is drilled and tapped for attaching the user-provided bracket. Cap screws for attaching the bracket are provided. H mounting also includes an output shaft (with milled flats) to provide the Double D rotary output either directly or through a user-provided coupling. Output shaft diameters and torque limits are listed in table 2. Dimensional information for the mounting plate and output shaft are shown in figures 4, 5, and 6.

Figure 2. Fisher 1052 Actuator with J Mounting Adaptation

W4139-1

The **J mounting adaptation** permits the actuator to be used for rotary actuation of Fisher keyed-shaft butterfly valve bodies and other keyed-shaft equipment. This mounting adaptation uses the standard butterfly valve mounting bracket and provides an output shaft with an attached coupling for keyed equipment shafts. Coupling sizes and torque limits are listed in table 3. Dimensional information for the mounting bracket and stub shaft coupling is shown in figures 4, 5, and 7.

Additionally, a top-mounted handwheel can be applied for infrequent service as a manual handwheel actuator. For more frequent manual operation, a side-mounted handwheel actuator is available. Also, an adjustable up travel stop can be added to limit the actuator stroke in the upward direction, or an adjustable down travel stop can be added to limit actuator stroke in the downward direction.

Specifications

Specifications are shown in table 1 for 1051 and 1052 actuators. Specifications for a given 1051 or 1052 actuator as it originally comes from the factory are stamped on a nameplate attached to the actuator.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

1051 and 1052 H & J Actuators

July 2023

Instruction Manual

D100320X012

Table 2. Output Shaft Diameters and Torque Limits for Actuators With H Mounting

ACTUATOR SIZE	OUTPUT SHAFT DIAMETER		TORQUE LIMIT FOR H MOUNTING	
	mm	Inches	N•m	Inch-Pounds
40	22.2	7/8	240	2120
	28.6	1-1/8	468	4140
	38.1	1-1/2	1110	9815
60	28.6	1-1/8	468	4140
	38.1	1-1/2	1210	10,680
70 ⁽¹⁾	38.1	1-1/2	1210	10,680

1. 1052 actuator only.

Table 3. Acceptable Shaft Diameters and Torque Limits for Actuators With J Mounting

ACTUATOR SIZE	COUPLING AVAILABILITY BY KEYED SHAFT DIAMETER		TORQUE LIMIT FOR J MOUNTING	
	mm	Inches	N•m	Inch-Pounds
40	9.5	3/8	52	460
	12.7	1/2	69	610
	15.9	5/8	114	1010
	19.1	3/4	207	1830
	25.4	1	468	4140
60	19.1	3/4	207	1830
	25.4	1	468	4140
	31.8	1-1/4	1030	9110
	38.1	1-1/2	1360	12,000
	50.8	2	2650	23,430
70 ⁽¹⁾	31.8	1-1/4	1030	9110
	38.1	1-1/2	1360	12,000
	50.8	2 ⁽²⁾	2650	23,430

1. 1052 actuator only.

2. Coupling supplied for mating with either 44.5 or 50.8 mm (1-3/4 or 2-inch) keyed shaft.

Principle of Operation

The diaphragm rod moves down as loading pressure is increased on top of the diaphragm. As the loading pressure is decreased, the spring forces the diaphragm rod upward.

The spring and diaphragm have been selected to meet the requirements of the application and, in service, the actuator should produce full travel of the valve or other operated equipment with the diaphragm pressure as indicated on the nameplate.

Consult the separate positioner instruction manual for actuator principle of operation with positioner.

Installation

WARNING

Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.

To avoid personal injury or property damage caused by bursting of pressure retaining parts, do not apply pressure exceeding the Maximum Diaphragm Casing Pressure limit given in table 1 or on the nameplate. Use pressure limiting or pressure relieving devices to prevent the casing pressure from exceeding the maximum diaphragm casing pressure.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

NOTICE

To avoid parts damage, do not apply pressure that exceeds the Maximum Diaphragm Sizing Pressure (table 1) or produces a torque greater than the Torque Limits (table 1, 2, or 3). Use pressure-limiting or pressure-relieving devices to prevent the diaphragm casing pressure from exceeding these limits.

Figure 3. Top Mounted Handwheel

ACTUATOR SIZE	H _c		J _c	
	mm	Inch	mm	Inch
40	281	11.06	356	14.00
60	359	14.12	432	17.00
70 ⁽¹⁾	335	13.62	356	14.00

1. Size 70 available in 1052 only.

Actuator Mounting

Use the following steps to connect the actuator to a valve body or other equipment. Unless otherwise specified, key numbers are shown in figures 12 and 13. Mounting dimensions are shown in figures 4, 5, 6, and 7.

Note

For an actuator with an H mounting adaptation and a 22.2 through 38.1 mm (7/8 through 1-1/2 inch) output shaft, find dimensions and center of gravity information in figures 3, 4, 5, 6, and 9, and approximate weights in table 8. This information is required for proper fabrication of the user-provided bracket and coupling.

1. For an actuator with an H mounting adaptation, attach an appropriate mounting bracket (not provided) to the mounting plate (key 22) with the cap screws (key 78). See figures 4, 5, and 6 for mounting dimensions on the mounting plate. Tighten the cap screws to the bolt torques listed in table 4.
2. Consult figure 10 for available mounting styles and positions. The actuator is normally positioned vertically with the valve body or other equipment in a horizontal pipeline.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

1051 and 1052 H & J Actuators

July 2023

Instruction Manual

D100320X012

Note

If the milled flats or the coupling on the end of the actuator output shaft (key 87) are oriented such that the output shaft cannot accommodate the operated equipment shaft, refer to the Changing Positions portion of the Changing Actuator Mounting section. This procedure describes how the output shaft can be repositioned to accommodate the operated equipment shaft.

3. If using an actuator with a **J mounting** adaptation, note that the valve shaft coupling (key 90) is furnished with two keyways lettered A and B as shown in figure 8 and 12 (letters C and D on the coupling are not used and can be disregarded). Align the appropriate keyway with the keyway in the operated equipment shaft. If using a Fisher butterfly valve, align the appropriate keyway on the coupling with the valve shaft keyway indicated in table 9. Then install the woodruff key (key 91) in the shaft keyseat, and slide the coupling onto the shaft. It is helpful to apply a light coat of grease to the inside of the coupling before sliding it onto the shaft.
4. For an actuator with an **H mounting** adaptation, slide the actuator (with the user-provided mounting bracket attached) into the user-provided coupling on the operated shaft. Then, secure the actuator to the operated equipment in the desired mounting position with the appropriate fasteners, such as mounting cap screws. See figures 4, 5 and 6 for output shaft dimensions.
5. For an actuator with a **J mounting** adaptation, secure the mounting bracket (key 22) to the valve body with the cap screws (key 78, not shown). Tighten the cap screws to the bolt torques in table 4. For 31.8 and 38.1 mm (1-1/4 and 1-1/2 inch) valve shafts, also place the two spacers (key 92, not shown) between the mounting bracket and valve body during this step.
6. For an actuator with a **J mounting** adaptation and a **50.8 mm (2-inch) output shaft** (key 87, figure 14), note that the valve shaft coupling (key 90, figure 14) is furnished with two keyways lettered A and B as shown in figure 8 (letters C and D on the coupling are not used and can be disregarded). Align the appropriate keyway with the keyway in the operated equipment shaft. Then, install the woodruff key (key 91, not shown in figure 14) in the shaft keyseat, and slide the coupling onto the shaft using the appropriate coupling keyway (see table 9 and figure 8). It is helpful to apply a light coat of grease to the inside of the coupling before sliding it onto the shaft. Secure the actuator (user-provided mounting bracket) to the operated equipment in the desired mounting position with the appropriate fasteners, such as mounting cap screws.
7. Follow the instructions given in the Turnbuckle Adjustment section before proceeding to the Loading Connection portion of this section.

	60	10	0.4	432	17.0
	70	23	0.9	488	19.2

Loading Connection

1. Connect the loading pressure piping to the pressure connection in the top of the diaphragm casing.

For size 40 through 60 actuators, run either NPS 1/4 pipe or 3/8-inch tubing between the NPT 1/4 pressure connection and the positioner or automatic controller.

For size 70 actuators, run either pipe or tubing between the pressure connection and the positioner or automatic controller. If necessary, remove the 1/4-inch bushing in the pressure connection to increase connection size.

2. Keep the length of pipe or tubing as short as possible to avoid transmission lag in the control signal. If an accessory (such as a volume booster or a positioner) is used, be sure that the accessory is properly connected to the actuator. If a positioner is part of the assembly, the pressure connection to the actuator will normally be made at the factory.
3. When the actuator is completely installed and connected to the instrument, check for correct action (air-to-open or air-to-close) to match the controlling instrument. For successful operation, the actuator stem and operating shaft must move freely in response to the loading pressure change on the diaphragm.

Adjustment

⚠ WARNING

Before performing any adjustment steps, follow the steps in the **WARNING** at the beginning of the Maintenance section.

1051 and 1052 Turnbuckle Adjustment

Correct turnbuckle adjustment ensures that the valve body or other operated equipment is correctly closed when the actuator is against its travel stops. The turnbuckle adjustment is the only adjustment necessary on the 1051 actuator. Key numbers used in this procedure are shown in figure 12 for 1051 actuators and in figure 13 for 1052 actuators.

For accurate adjustment, remove the valve body or other operated equipment from the pipeline.

A regulated air supply will be required to stroke the actuator. Consult table 10 for the sizes of the three open end wrenches required for this procedure.

1. Remove the access plate (key 59). Also remove the machine screws (key 60), if present.

Note

For the most accurate adjustment of the actuator, do not remove the cover (key 33) during this procedure.

2. Loosen the lower locknut (key 16).

Table 10. Wrench Sizes Required for Turnbuckle Adjustment, Inches

Actuator	Size	Turnbuckle (Key 57)	Lower Locknut (Key 16)	Upper Locknut (Key 58)
1051 & 1052	40	1-1/8	3/4	1-1/8
	60	1-5/16	15/16	1-5/16
1052	70	1-5/16	1-1/8	1-5/16

3. Make sure the actuator housing (key 20) is clear of any tools or other instruments that could obstruct the actuator stroke path. Pressure the diaphragm casing enough to stroke the actuator down so that the left-hand threaded upper locknut (key 58) is accessible through the access opening. Loosen the locknut.
4. Use one of the following:
 - a. **For push-down-to-close action**—Slowly stroke the actuator to the down travel stop. Consult the appropriate instruction manual for determining the closed position of the valve body or other operated equipment. Adjust the turnbuckle (key 57) until the closed position is reached. Lock this adjustment with the left-hand threaded locknut (key 58). Stroke the actuator to the mid-travel position, and tighten the locknut (key 16). Tighten each locknut to the appropriate torque value listed in table 11.
 - b. **For push-down-to-open action**—Consult the appropriate instruction manual for determining the closed position of the valve or other operated equipment. Release all pressure from the diaphragm casing, making sure the diaphragm is against its up travel stop. Be sure that the optional handwheel is adjusted to its topmost position so that the closed position of the actuator and valve body or other operated equipment can be reached simultaneously. Check the position of the valve body or other operated equipment with respect to its properly closed position. Stroke the actuator so the turnbuckle (key 57) is accessible through the access opening. Adjust the linkage. Release pressure to the actuator, and check the new adjustment. Continue this procedure until the operated equipment is in the closed position when the actuator is resting on its up travel stop. Tighten locknut

(key 16). Stroke the actuator, and tighten the left-hand threaded locknut (key 58). Tighten each locknut to the appropriate torque value listed in table 11.

5. Replace the access plate (key 59). Also, replace the machine screws (key 60), if present.

6. Loosen the self-tapping screws (key 38), and adjust the travel indicator (key 37). Retighten the self-tapping screws.

1052 Spring Adjustment

Initial Compression

The 1052 nameplate specifies a spring set, which is the initial compression adjusted into the actuator spring. Initial compression is the casing pressure at which the diaphragm and diaphragm rod begin to move away from the up travel stop with the actuator disconnected from the valve body or other operated equipment. (With the actuator connected and pressure applied to the valve body or other operated equipment, a higher casing pressure will be required to start actuator travel). The initial compression was selected (based upon the service conditions specified when the actuator was ordered) so that when the actuator and valve body or other operated equipment are in service, the operated equipment will close properly and full travel will be obtained within a diaphragm casing pressure range of 0 to 1.2, 0 to 2.3, 0 to 2.8 or 0 to 3.8 bar (0 to 18, 0 to 33, 0 to 40, or 0 to 55 psig) depending on specific actuator size and construction.

If the actuator has been disassembled or if the spring adjustment was changed, and it is desired to match the initial compression stated on the nameplate, make sure the rod end bearing (key 17, figure 13) has been disconnected from the lever (key 27, figure 13). Adjust the spring so that the diaphragm rod just starts to travel at the spring set pressure specified on the nameplate. Be sure the rod end bearing does not hit the lever as the diaphragm and diaphragm rod move away from the up travel stop.

To adjust the spring, insert a round rod into one of the slots in the lower bearing seat (key 73, figure 13). Slot diameter is 9.5 mm (3/8-inch) for size 40 actuators, 15.9 mm (5/8-inch) for size 60 actuators, and 19.1 mm (3/4-inch) for size 70 actuators.

Rotate the bearing seat to move it toward the casings (keys 1 and 2, figure 13) to increase initial compression or away from the casings to decrease initial compression.

Table 11. Recommended Bolting Torques⁽¹⁾

KEY NUMBER	ACTUATOR SIZE					
	40		60		70	
	N•m	lbf•ft	N•m	lbf•ft	N•m	lbf•ft
6	27	20	27	20	27	20
7 & 8	41	30	41	30	102	75
9	34	25	102	75	102	75
16	34	25	61	45	102	75
18	81	60	163	120	271	200
21	23	17	68	50	68	50
23	34	25	81	60	81	60
28	81	60	163	120	271	200
34	34	25	81	60	81	60
40	9	7	9	7	9	7
54 handwheel	34	25	34	25	34	25
54 down stop	27	20	66	49	69	51
58	102	75	163	120	163	120
141	41	30	41	30	81	60

1. Exceeding any torque requirements could damage the actuator and impair safe operation.

Stroking Range

The initial spring set listed on the nameplate has been determined to be the optimum setting, and it is not recommended to make spring adjustments that will cause this value to change or be exceeded. For push-down-to-open (PDTO) action, the initial spring set is normally the maximum allowable to provide the maximum spring closing force. Any increase of this setting could over-stress the spring at full travel. For push-down-to-close (PDTC) action, the initial spring set has been determined to be the optimum balance between the air to close and the spring to open breakout torque.

If the 1052 actuator is to be changed from one action to another (i.e., from PDTC to PDTO), first refer to the initial spring compression values listed in the table for keys 11 and 13 in the Parts List section. Then adjust the unit according to the procedures in the Initial Compression portion of this section.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions. Instructions are given below for disassembly and assembly of parts. Key numbers referenced in the following steps are shown in figure 12 for 1051 actuators and in figure 13 for 1052 actuators unless otherwise specified.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.

- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Disassembly

The following procedure describes how the actuator can be completely disassembled. When inspection or repairs are required, perform only those steps necessary to accomplish the procedure. Do not under ordinary circumstances remove the cap screws (keys 7, 8, and 21).

NOTICE

Cap screw (key 18) must be disengaged from the lever (key 27) before removing the diaphragm casing (key 1). Failure to do so will allow the spring precompression to rotate the valve body or other operated equipment beyond its fully open or closed position. This could cause damage to the operated equipment.

1. Bypass the valve or other operated equipment. Relieve all actuator loading pressure, and remove the tubing or pipe from the top of the actuator.
2. Remove the positioner, if one is used.
3. Mark the orientation of the travel indicator (key 37) with respect to the travel indicator scale (key 35). Then, unscrew the cap screws and washers (keys 34 and 63), and remove the cover (key 33).
4. Remove the retaining ring (key 30), and then remove the hub (key 29) from the cover.
5. Check the condition of the bearing (key 31). If replacement of the bearing is necessary, the travel indicator scale (key 35) must first be removed by removing the self-tapping screws (key 36). Mark the orientation of the travel indicator scale on the cover before removing it.

NOTICE

When removing the actuator from the valve body, do not use a hammer or similar tool to drive the lever (key 27) or actuator off the output shaft (key 87). Driving the lever or actuator could damage operated equipment. For valves, driving the lever (key 27) could move the valve disk and bearings away from the centered position causing subsequent damage to valve parts.

If necessary, use a wheel puller to remove the lever. It is permissible to tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could also damage operated parts or disrupt the centered position of a valve disk or other equipment.

6. For an actuator with an H mounting adaptation and a 22.2 through 38.1 mm (7/8 through 1-1/2 inch) output shaft, unscrew the cap screws (key 78) and remove the actuator from the operated equipment. Mark the orientation of the lever (key 27) with respect to the output shaft (key 87). This marking is used during reassembly to allow for proper lever/output shaft positioning.

Then, loosen the cap screw (key 28) so that the output shaft is free to slide off the lever. With the lever and output shaft properly marked, unscrew the cap screws (key 23) and remove the mounting plate (key 22) and output shaft (key 87) assembly from the actuator housing (key 20). If necessary, remove the retaining ring (key 88) and separate the output shaft from the mounting plate.

7. For an actuator with a J mounting adaptation (see figures 12 and 13) with a 50.8 mm (2-inch) output shaft (see figure 14) and proceed as follows:
 - a. Remove the cap screws (key 78, not shown in figures 12 and 13) and remove the actuator from the operated equipment. For an actuator with J mounting and a 31.8 or 38.1 mm (1-1/4 or 1-1/2 inch) valve shaft diameter, two spacers (key 92, not shown in figures 12 and 13) are also removed with the cap screws (key 78).
 - b. When separating the output shaft (key 87) and coupling (key 90) from the operated shaft, remember to remove the woodruff key (key 91, not shown in figure 14) from the operated shaft keyway.
 - c. Mark the orientation of the lever (key 27, figures 12 and 13) with respect to the output shaft (key 87). This marking is used during reassembly to allow for proper lever/output shaft positioning.
 - d. Loosen the cap screw (key 28, figures 12 and 13) so that the output shaft is free to slide off the lever.
 - e. With the lever and output shaft properly marked, unscrew the cap screws (key 23) and remove either the mounting bracket (key 22, figures 12 and 13 for J mounting) or the mounting plate (key 22, figure 14 for H mounting) plus the attached output shaft (key 87) from the actuator housing (key 20).
 - f. If necessary, remove the retaining ring (key 88) and slide the mounting bracket or mounting plate off the output shaft.
8. Check the bearing (key 67) in the mounting bracket or mounting plate (key 22). Press out and replace the bearing if necessary.
9. Heat the hex nut (key 19) to 177°C (350°F) long enough for the thread-locking adhesive (high strength) (key 77) to lose its holding strength. Then, remove the cap screw and hex nut (keys 18 and 19), and remove the lever (key 27) from the housing.
10. Rotate the handwheel (if one is used) counter-clockwise until the handwheel is not compressing the spring (key 11).

⚠ WARNING

To avoid personal injury from precompressed spring force suddenly thrusting the upper diaphragm casing (key 1) away from the actuator, relieve 1052 spring compression, or carefully remove 1051 casing cap screws by following the instructions presented in the next two steps before proceeding further.

11. To relieve 1052 spring compression, insert a round rod into one of the slots in the lower bearing seat (key 73). Slot diameter is 9.5 mm (3/8 inch) for size 40 actuators, 15.9 mm (5/8 inch) for size 60 actuators, and 19.1 mm (3/4 inch) for size 70 actuators. Use the rod to rotate the lower bearing seat, and move it away from the actuator casings. Continue rotating the lower bearing seat until spring compression is completely removed.
12. Loosen, but do not remove, all casing cap screws (key 5). Make sure there is no spring force on the 1051 upper diaphragm casing. Unscrew and remove the cap screws and hex nuts (keys 5 and 6), and then remove the upper diaphragm casing and the diaphragm (key 3).
13. Proceed as appropriate:

For 1051 actuators,

- a. Read and follow the warning printed on the nameplate (key 56) located on the diaphragm plate (key 4).

- b. Pull the diaphragm plate (key 4) and attached parts out of the actuator. The spring (key 11), diaphragm rod (key 10), cap screw (key 9), spring seat (key 13), hex nut (key 58), turnbuckle (key 57), hex nut (key 16), and rod end bearing (key 17) will be attached to the diaphragm head.

⚠ WARNING

For 1051 actuators, the diaphragm plate (key 4) may be wedged against the diaphragm rod (key 10), thereby preventing the spring compression from being relieved as the cap screw (key 9) is loosened. Dislodge the diaphragm head from the diaphragm rod by loosening the cap screw (key 9) one full turn and tapping the underside of the diaphragm head until it follows the cap screw disassembly. Failure to check for this situation before removing the cap screw (key 9) could cause personal injury due to the sudden release of spring compression as the cap screw is disengaged.

- c. Slowly remove the cap screw (key 9) while making sure that the diaphragm head is following the cap screw removal. Note that spring load will be zero before the cap screw is completely removed. Then separate the remaining parts of the assembly.

For 1052 actuators,

- a. Remove the rod end bearing (key 17), the hex nut (key 16), the turnbuckle (key 57), and the hex nut (key 58) from the diaphragm rod (key 10).
 - b. Pull the diaphragm plate (key 4) and attached parts out of the actuator. Then remove the cap screw (key 9) to separate the diaphragm plate and the diaphragm rod.
 - c. Proceed as appropriate:
- For actuator designs **without** a set screw in the spring barrel (key 12), remove the actuator spring (key 11) from the actuator. If it is necessary to remove the adjustor (key 74) from the spring barrel during this procedure, heat the base of the adjustor to 177°C (350°F) long enough for the thread locking adhesive (high strength) (key 77) to lose its holding strength. Then, unscrew the adjustor from the spring barrel. If the spring seat and the lower bearing seat (key 13 and 73) are to be replaced, unscrew the lower bearing seat from the adjustor, and then remove the thrust bearing and the bearing races (keys 71 and 72) from the lower bearing seat.
 - For actuator designs **with** a set screw, (key 75), remove the actuator spring (key 11) from the actuator. If the spring seat and the lower bearing seat (keys 13 and 73) are to be replaced, unscrew the lower bearing seat from the adjustor, and then remove the thrust bearing and the bearing races (keys 71 and 72) from the lower bearing seat. If it is necessary to remove the spring adjustment parts, heat the set screw (key 75) to 177°C (350°F) long enough for the thread-locking adhesive (high strength) (key 77) to lose its holding strength, and then loosen the set screw (key 75). Unscrew the spring adjustor (key 74) from the spring barrel (key 12).

Assembly

This procedure assumes that the actuator is completely disassembled. If the actuator is not completely disassembled, start these instructions at the appropriate step. Key numbers used are shown in figure 12 for 1051 actuators and in figure 13 for 1052 actuators.

1. If the 1052 spring barrel (key 12) was removed from the housing (key 10), align the spring barrel to the housing as described below to ensure that the offset hole in the base of the spring barrel is located properly.

For size 40 and 60 actuators, note that one of the accessory mounting bosses on the spring barrel is closer to the diaphragm end of the spring barrel. Place the spring barrel on the housing with the upper boss (the one closer to the diaphragm end) on the same side as the boss located on the housing (see figure 13). This ensures proper positioning of the offset hole. Secure the spring barrel with the cap screws (key 21).

For size 70 actuators, the spring barrel need not be aligned in any particular position when placing it on the housing.

Note

Refer to table 11 for bolting torques for actuator bolts and cap screws.

2. Proceed as appropriate:

For 1051 actuators,

- a. Coat the thread of the cap screw (key 9) and the tapered end of the diaphragm rod (key 10) with lithium grease (key 76).
- b. Assemble the diaphragm rod, spring seat (key 13), spring (key 11), and diaphragm plate (key 4), and secure with the cap screw (key 9). Tightening the cap screw will compress the spring. Be certain the tapered end of the diaphragm rod is seated in the corresponding hole in the diaphragm plate, that the spring is seated in the spring seat, and that the cap screw is tightened to the torque specified in table 11.
- c. Install the hex nut (key 58), turnbuckle (key 57), hex nut (key 16), and rod end bearing (key 17) onto the diaphragm rod.
- d. Be certain the travel stops (key 8) are located as shown in figure 11.
- e. Install the diaphragm plate and attached parts into the actuator.
- f. Be sure the warning nameplate (key 56) is in place. Install the diaphragm (key 3) and the upper diaphragm casing (key 1). Install the cap screws and hex nuts (keys 5 and 6). Tighten the cap screws evenly in a crisscross pattern to compress the spring and secure the upper diaphragm casing. Tighten these cap screws to the torques shown in table 11.

For 1052 actuators,

- a. Proceed as appropriate:
- For actuator designs without a set screw in the spring barrel (key 12), if the adjustor and attached parts were removed, first clean and then lubricate the upper threads of the adjustor (key 74) with lithium grease (key 76) as shown in figure 13. Install the lower bearing seat (key 73), the thrust bearing (key 71), the thrust bearing races (key 72), and the spring seat (key 13) onto the adjustor. Then, first clean and then coat the lower end of the adjustor with thread-locking adhesive (high strength) (key 77) as shown in figure 13, and install the entire assembly into the spring barrel (key 12). Let the adjustor stand undisturbed for at least two hours after installation to allow the thread-locking compound to cure.

NOTICE

When applying lubricant to the upper threads and thread-locking compound to the lower threads of the adjustor, do not overlap the coat of lubricant with the coat of thread-locking compound since this will adversely affect the performance quality of both substances.

- For actuator designs with a set screw, (key 75), if the adjustor (key 74) and attached parts were removed, lubricate the threads of the adjustor with lithium grease (key 76). Install the lower bearing seat (key 73), the thrust bearing

- (key 71), the thrust bearing races (key 72), and the spring seat (key 13) onto the adjustor. Install this assembly into the spring barrel (key 12). After first cleaning and then coating the set screw (key 75) with thread-locking adhesive (high strength) (key 77), secure the adjustor with the set screw (key 75).
- b. Coat the tapered end of the diaphragm rod (key 10) and the threads of the cap screw (key 9) with lithium grease (key 76). Bolt the diaphragm plate (key 4) to the diaphragm rod with the cap screw (key 9). Tighten the cap screw to the torque value listed in table 11.
- c. Be certain the travel stops (key 8) are located as shown in figure 11.
- d. Install the spring (key 11) into the spring barrel. Install the diaphragm plate and diaphragm rod into the actuator. Attach the hex nut (key 58), turnbuckle (key 57), hex nut (key 16), and rod end bearing (key 17) to the diaphragm rod.
- e. Install the diaphragm (key 3).
- f. Place the upper diaphragm casing (key 1) on the lower diaphragm casing (key 2). If necessary, rotate the lower bearing seat (key 73) so that the upper diaphragm casing travel stop will not contact the diaphragm when the casing cap screws (key 5) are tightened. Secure the upper diaphragm casing with the cap screws and hex nuts (keys 5 and 6) in a criss-cross pattern to the torques shown in table 11. Be sure the warning nameplate is in place on the casing.
3. If the bearing (key 67) was removed, press in the new bearing. The end of the bearing should be flush with the outside of the mounting bracket or mounting plate (key 22).
4. For an actuator with an **H mounting** adaptation, install the output shaft (key 87) through the mounting plate (key 22) and secure it with the retaining ring (key 88). Then, attach the mounting plate and output shaft assembly to the actuator housing (key 20) with the cap screws (key 23). Tighten the cap screws to the appropriate torque value listed in table 11.
5. For an actuator with a **J mounting** adaptation, refer to figures 12 and 13. Install the output shaft (key 87) with attached coupling (key 90) through the mounting bracket (key 22) and secure it with the retaining ring (key 88). Attach the mounting bracket and output shaft assembly to the actuator housing (key 20) with the cap screws (key 23). Tighten the cap screws to the appropriate torque value listed in table 11.
6. For an actuator with a **J mounting** adaptation and a **50.8 mm (2-inch) output shaft**, refer to figure 14. Install the output shaft (key 87) with attached coupling (key 90) through the mounting plate (key 22) and secure it with the retaining ring (key 88). Attach the mounting plate and output shaft assembly to the actuator housing with the cap screws (key 23). Tighten the cap screws to the appropriate torque value listed in table 11.
7. Apply lithium grease (key 76) to the output shaft splines. Then, align the lever (key 27) and output shaft so that the marking that was made in step 6 or 7 of the Disassembly procedure is oriented correctly. Slide the lever into place. When installing the lever, align the bolt holes in the lever as close as possible with the hole in the rod end bearing (key 17). Temporarily rotate the lever and output shaft until the rod end bearing no longer interferes with further installation of the lever. Then, slide the lever as far as it can go onto the output shaft.
8. Clamp the lever to the output shaft with the cap screw (key 28). Tighten the cap screw to the torque value listed in table 11.
9. For 1052 actuators, complete the Initial Compression portion of the Adjustment section before proceeding.
10. Rotate the lever (key 27) to align with the rod end bearing (key 17). This connection can be aided by stroking the actuator off its up travel stop with a regulated air source.

Figure 10. Actuator Housing Construction Styles and Mounting Positions

DESIRED ACTION OF		HOUSING CONSTRUCTION TO SPECIFY
Actuator	Operated Equipment	
Push Down to Open ⁽¹⁾ (PDTO)	Clockwise to Close ⁽³⁾	Style A
	Counterclockwise to Close ⁽³⁾	Style B
Push Down to Close ⁽²⁾ (PDTC)	Clockwise to Close ⁽³⁾	Style B
	Counterclockwise to Close ⁽³⁾	Style A

1. This action uses the spring to close the valve body or other equipment.
2. This action uses the spring to open the valve body or other equipment.
3. When viewed from actuator side of valve body or other equipment.

NOTE:
1 DOTTED LINES INDICATE ALTERNATE MOUNTING POSITIONS 2, 3, AND 4.

43A6505-A
A1578-3

11. Apply thread-locking adhesive (high strength) (key 77) to the threads of the cap screw (key 18).
12. Connect the lever (key 27) and the rod end bearing (key 17) with the cap screw and hex nut (keys 18 and 19). Tighten the cap screw to the torque value listed in table 11.
13. If a positioner is to be used, consult the separate positioner instruction manual for proper positioner installation.
14. Coat the bearing surfaces of the hub (key 29) and cover (key 33) with lithium grease (key 76). Install the bearing (key 31) and hub into the cover. Secure with the retaining ring (key 30).
15. Install the travel indicator scale (key 35) so that the markings on the scale and cover that were made in step 5 of the Disassembly procedure are oriented correctly. Secure the travel indicator scale to the cover with the self-tapping screws (key 36). Then install the travel indicator (key 37), and secure it with the self-tapping screws (key 38).
16. Position the travel indicator (key 37) so that the markings on the travel indicator and travel indicator scale that were made in step 3 of the Disassembly procedure are oriented correctly. Then, replace the cover (key 33), and secure it with the cap screws and washers (keys 34 and 63). If the holes in the cover and housing (key 20) do not align, use a regulated air source to move the actuator slightly off the up travel stop. If hole alignment cannot be obtained in this manner, temporarily loosen the cap screws (key 23), and shift the housing slightly. Do not stroke the actuator while the cover is off. Tighten the cap screws to the torque value listed in table 11.
17. Follow the instructions in the Actuator Mounting section for correct actuator mounting and adjustment. Remember to replace the access plate (key 59) when performing this procedure.

Changing Actuator Mounting

The actuator is normally positioned vertically in a horizontal pipeline. However, each style can be mounted in two possible mounting styles and four possible positions (see figure 10).

Note

Due to its weight, the 1052, size 70 actuator must be externally supported if mounted in the horizontal position.

⚠ WARNING

Before performing any Actuator Mounting steps, follow the steps in the WARNING at the beginning of the Maintenance section.

Use the following procedures along with figures 12 and 13 for key number references to convert from style A to style B or vice versa or to change the mounting position.

Changing Styles

1. Unscrew the cap screws and washers (keys 34 and 63), and remove the cover (key 33).
2. Heat the hex nut (key 19) to 177°C (350°F) long enough for the thread-locking adhesive (high strength) (key 77) to lose its holding strength. Then, remove the cap screw and hex nut (keys 18 and 19).
3. Loosen the cap screw (key 28).

NOTICE

If necessary, use a wheel puller to remove the lever (key 27) from the output shaft (key 87). It is permissible to tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could damage the operated equipment.

4. Mark the side of the lever (key 27) that is nearest to the end of the output shaft (key 87). This marking is used during reassembly to determine which side of the lever should be inserted into the actuator housing first. When the lever is marked, remove the lever.
5. For an actuator with a J mounting adaptation,
 - a. Unscrew the cap screws (key 23), and remove the actuator housing (key 20) from the mounting bracket (key 22).
 - b. Rotate the actuator housing 180 degrees, maintaining the appropriate position (1, 2, 3, or 4), and place the actuator onto the mounting bracket (key 22).
 - c. Secure the actuator housing to the mounting bracket with the cap screws (key 23). Tighten the cap screws to the torque value listed in table 11.
6. For an actuator with an H mounting adaptation,
 - a. Unscrew the cap screws (key 78) and remove the actuator assembly from its mounting bracket.

- b. Unscrew the cap screws (key 23) and remove the mounting plate (key 22) and output shaft (key 87) assembly from the actuator housing. Remount the assembly on the opposite side of the actuator, and secure it to the housing with the cap screws (key 23). Tighten the cap screws to the torque value listed in table 11.
 - c. Rotate the actuator housing 180 degrees, maintaining the appropriate position (1, 2, 3, or 4) and secure the actuator housing to the mounting bracket with the cap screws (key 78). Tighten the cap screws to the torque value listed in table 4.
7. Install the lever (key 27) as follows:
 - a. For push-down-to-open action, rotate the operated equipment to the fully closed position.
 - b. For push-down-to-close action, rotate the operated equipment to the fully open position.
 - c. With the operated equipment oriented correctly, slide the lever onto the output shaft (key 87) with the end marked in step 4 inserted first. When installing the lever, align the bolt holes in the lever as close as possible with the hole in the rod end bearing (key 17).
 - d. Temporarily rotate the lever and output shaft until the rod end bearing no longer interferes with further installation of the lever. Then, slide the lever as far as it can go onto the output shaft. Clamp the lever to the output shaft with the cap screw (key 28). Tighten the cap screw to the torque value listed in table 11.
 - e. Rotate the lever and output shaft back to the original position (i.e., operated equipment fully closed for push-down-to-open action or operated equipment fully open for push-down-to-close action). Then, adjust the rod end bearing so that it can be attached to the lever.
8. Apply thread-locking adhesive (high strength) (key 77) to the threads of the cap screw (key 18).
9. Connect the lever (key 27) and the rod end bearing (key 17) with the cap screw and hex nut (keys 18 and 19). This connection can be aided by stroking the actuator from its up travel stop with a regulated air source. Tighten the cap screw to the torque value listed in table 11.
10. Note the position of the valve body or other operated equipment and direction of rotation. Position the travel indicator (key 37) accordingly. Replace the cover (key 33), and secure it with the cap screws and washers (keys 34 and 63). If the holes in the cover and housing (key 20) do not align, use a regulated air source to move the actuator slightly off the up travel stop. If hole alignment cannot be obtained in this manner, temporarily loosen the cap screws (key 23), and shift the housing slightly. Do not stroke the actuator while the cover is off. Tighten both sets of cap screws to the torque values listed in table 11.
11. Follow the instructions in the Turnbuckle Adjustment section.

Changing Positions

1. Unscrew the cap screws and washers (keys 34 and 63), and remove the cover (key 33).
2. Mark the orientation of the lever (key 27) with respect to the output shaft (key 87). This marking is used during reassembly to allow for proper lever/output shaft positioning. When the lever and output shaft are properly marked, heat the hex nut (key 19) to 177°C (350°F) long enough for the thread-locking adhesive (high strength) (key 77) to lose its holding strength. Then, remove the cap screw and hex nut (keys 18 and 19).

NOTICE

If necessary, use a wheel puller to remove the lever (key 27) from the output shaft (key 87). You may tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could damage the operated equipment.

3. Loosen the cap screw (key 28) and remove the lever (key 27) from the output shaft (key 87).

4. For an actuator with a J mounting adaptation.
 - a. Unscrew the cap screws (key 23), and remove the actuator housing (key 20) from the mounting bracket (key 22).
 - b. Rotate the actuator housing to the new position (1, 2, 3, or 4).
 - c. Secure the actuator housing to the mounting bracket with the cap screws (key 23). Tighten the cap screws to the torque value listed in table 11.
5. For an actuator with an H mounting adaptation.
 - a. Unscrew the cap screws (key 78) and loosen the actuator assembly from its mounting bracket.
 - b. Rotate the actuator housing to the new position (1, 2, 3, or 4).
 - c. Secure the actuator housing to the mounting bracket with the cap screws (key 78). Tighten the cap screws to the torque value listed in table 4.
6. Referring to the alignment marks that were made in step 2, install the lever (Key 27) onto the output shaft (key 87) as follows:
 - a. If the new actuator position is 90 degrees clockwise from the previous actuator position, install the lever so that its orientation mark is located 90 degrees clockwise from the mark on the output shaft.
 - b. If the new actuator position is 90 degrees or 180 degrees counterclockwise from the previous position, install the lever so that its orientation mark is located either 90 degrees (for 90 degrees) or 180 degrees (for 180 degrees) counterclockwise (respectively) from the mark on the output shaft.
 - c. Slide the lever onto the output shaft with the bolt holes in the lever aligned as closely as possible with the hole in the rod end bearing (key 17). Then, temporarily rotate the lever and output shaft until the rod end bearing no longer interferes with further installation of the lever, and slide the lever as far as it can go onto the output shaft. Clamp the lever to the output shaft with the cap screw (key 28). Tighten the cap screw to the torque value listed in table 11.
 - d. Rotate the lever and output shaft back to the original position, and then adjust the rod end bearing so that it can be attached to the lever.
7. Apply thread-locking adhesive (high strength) (key 77) to the threads of the cap screw (key 18).
8. Connect the lever (key 27) and the rod end bearing (key 17) with the cap screw and hex nut (keys 18 and 19). This connection can be aided by stroking the actuator from its up travel stop with a regulated air source. Tighten the cap screw to the torque value listed in table 11.
9. Note the position of the valve body or other operated equipment and direction of rotation. Position the travel indicator (key 37) accordingly. Replace the cover (key 33), and secure it with the cap screws and washers (keys 34 and 63). If the holes in the cover and housing (key 20) do not align, use a regulated air source to move the actuator slightly off the up travel stop. If hole alignment cannot be obtained in this manner, temporarily loosen the cap screws (key 23), and shift the housing slightly. Do not stroke the actuator while the cover is off. Then, tighten both sets of cap screws to the torque values listed in table 11.
10. Follow the instructions in the Turnbuckle Adjustment section.

Figure 11. Travel Stop Orientation

A2534-1

Top-Mounted Handwheels and Adjustable Travel Stops

Handwheel and Travel Stop Operation

Note

If repeated or daily manual operation is expected or desired, the unit should be equipped with a manual handwheel actuator. Refer to the separate manual handwheel actuator instruction manual for mounting instructions.

The top-mounted handwheel assembly is attached to a special upper diaphragm casing (key 1, figures 12 and 13) with cap screws (key 141, figure 15). A hex nut (key 137, figure 15) locks the handwheel in position.

Turning the handwheel (key 51, figure 15) clockwise into the upper diaphragm casing forces the pusher (key 135, figure 15) against the diaphragm and diaphragm plate (keys 3 and 4, figures 12 and 13) to compress the spring (key 11, figures 12 and 13) and move the diaphragm rod downward. Turning the handwheel counterclockwise allows the actuator spring to move the diaphragm rod upward. If the action is push-down-to-close, full opening can be restricted by positioning the handwheel at the desired position. If the action is push-down-to-open, full closing can be restricted by use of the handwheel.

The adjustable up travel stop (figure 16) limits the actuator stroke in the upward direction. To make adjustments, first relieve actuator loading pressure before removing the closing cap (key 187) as it is a pressure retaining part. Also, for size 70 actuators, the hex nut (key 137) must be loosened.

Turning the stem (key 133) clockwise into the diaphragm case moves the actuator stem downward or counterclockwise to allow the spring to move the actuator stem upward. If the action is push-down-to-close, full opening can be restricted; or if the action is push-down-to-open, full closing can be restricted by the position of the adjustable travel stop.

The adjustable down travel stop (figure 17) limits the actuator stroke in the downward direction. To make adjustments, first relieve actuator loading pressure before removing the closing cap (key 187) as it is a pressure retaining part. After removing the closing cap, loosen the hex jam nut (key 189) and either turn the hex nut (key 63 for size 40, and 70 actuators; or key 54 for size 60 actuators) down on the stem (key 133) to limit travel, or up on the stem to allow more travel. Lock the jam nut against the hex nut and replace the closing cap after the adjustment has been made. For size 70, tighten the hex nut and replace the closing cap after adjustment.

Handwheel and Travel Stop Maintenance

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If loading pressure seems to be leaking from either the handwheel or adjustable up stop, the O-rings (key 138 and 139, figures 15 and 16) may need replacement. If the adjustable down stop leaks, the O-ring (key 139, figure 17) may need replacement or possibly the closing cap (key 187, figure 17) is not tight. To tighten the closing cap, apply a good grade of thread sealant to the closing cap threads.

For ease of operation, the stem (key 133, figures 15, 16, and 17) threads may need an occasional application of lithium grease. A grease fitting (key 169, figures 15 and 16) is provided for this purpose in the size 70. The size 70 may also need to have the thrust bearing (key 175, figures 15 and 16) packed with lithium grease. Travel stops for the smaller casings can be lubricated between the stem and pusher (key 135, figures 15 and 16) with lithium grease.

1. Bypass the control valve, reduce loading pressure to atmospheric, and remove the tubing or pipe from the body (key 142, figures 15, 16, and 17).

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1, figures 12 and 13) away from the actuator, either relieve 1052 spring compression, or carefully remove 1051 casing cap screws by following the instructions that are referenced in the steps below before removing the casing.

2. Relieve all actuator spring compression by following the procedures presented in the Disassembly portion of the Maintenance section. Then, rotate either the handwheel (key 51, figure 15) or the travel stop stem (key 133, figures 16 and 17) counterclockwise until the handwheel or travel stop assembly is no longer compressing the spring.
3. Proceed as appropriate:

For Top-Mounted Handwheels and Adjustable Up Travel Stops

- a. Remove the upper diaphragm casing (key 1, figures 12 and 13) by following steps 1, 3, 6, 7, 9, 11, and 12 of the Disassembly portion of the Maintenance section.
- b. Remove the cap screws (key 141, figures 15 and 16, and separate the assembly from the upper casing.
- c. Loosen the locknut (key 137, figure 15) or remove the closing cap (key 187, figure 16).
- d. Turn the stem (key 133, figures 15 and 16) clockwise out of the body. On handwheel assemblies, the cotter pin and slotted nut (keys 247 and 54, figure 15) will have to be removed so that the handwheel (key 51, figure 15) and locknut can be taken off the stem first.
- e. Remove and inspect the O-rings (keys 138 and 139, figures 15 and 16); replace them if necessary.
- f. To complete disassembly for sizes 40 and 60, drive out the groove pin (key 140, figures 15 and 16), and slide the pusher (key 135, figures 15 and 16) off the stem. The pusher of a size 70 unit is held to the stem by a retaining screw (key 174, figures 15 and 16). Removing the retaining screw and pusher exposes the thrust bearing (key 175, figures 15 and 16) for inspection.

For Adjustable Down Travel Stops

Refer to figure 17 for appropriate key numbers unless otherwise stated.

- a. Remove the closing cap (key 187), and unscrew the jam nut and hex nut (keys 189 and 63 for sizes 40, and 70 actuators; or keys 189 and 54 for size 60 actuators) off the stem (key 133).
 - b. Remove the upper diaphragm casing (key 1, figures 12 and 13) and travel stop body (key 142) by following steps 1, 3, 6, 7, 9, 11, and 12 of the Disassembly portion of the Maintenance section.
 - c. Unscrew cap screws (key 141), and remove the body from the diaphragm case.
 - d. Check the condition of the O-ring (key 139), and replace it if necessary.
 - e. Loosen the hex nut (key 54), and then unscrew the travel stop stem (key 133) out of the actuator stem. The lower diaphragm plate (key 82) can now be removed and the rest of the actuator disassembled.
4. Reassemble by reversing the order of the steps you took to disassemble, being sure to apply lubricant as previously mentioned and as shown by the lubrication boxes (key 241) in figures 15 and 16. For size 70 handwheels or up travel stop assemblies, coat the threads of the retaining screws (key 174, figures 15 and 16) with thread-locking adhesive (high strength) (key 242).

5. Adjust the spring to obtain the appropriate travel stop restriction by following the procedures presented in the introductory portion of this section, and then return the unit to operation.

Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, refer to the serial number found on the actuator nameplate (key 41, figure 12).

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts List

Retrofit Kits

Kit provides parts to add a top-mounted handwheel. Kit number 1 includes the handwheel assembly only. Kit number 2 includes Kit number 1 and a new upper case (key 1) that is required to mount the handwheel assembly.

W4140-1

Introduction

Scope of Manual

This instruction manual includes installation, adjustment, operation, maintenance, and parts ordering information for the Fisher 1052 size 20 diaphragm rotary actuator with H mounting (figure 1) and the optional top-mounted handwheel (see figure 7). Instructions for the rotary positioner and other accessories are included in separate instruction manuals.

Do not install, operate, or maintain a 1052 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Table 1. Specifications

Operating Principle Direct-Increasing loading pressure forces the diaphragm rod from the top to the bottom of the casing Casing Pressure Ranges ■ 0 to 1.2 bar (10 to 18 psig), ■ 0 to 2.3 bar (0 to 33 psig), or ■ 0 to 2.8 bar (0 to 40 psig) depending on spring used for proportional control; up to 3.4 bar (50 psig) for on-off control Maximum Allowable Sizing Pressure⁽¹⁾ 3.4 bar (50 psig) Maximum Allowable Casing Pressure⁽²⁾ 4.1 bar (60 psig) Maximum Rotation 90 degrees (travel is adjustable between 60 degrees and 90 degrees by travel stops) Maximum Allowable Output Torque 58 N•m (515 lbf•in)	Stroking Time Depends on degrees of rotation, spring rate, initial spring compression, and supply pressure. If stroking time is critical, consult your Emerson sales office. Material Temperature Capabilities⁽²⁾ -40 to 180°F (-40 to 82°C) Pressure Connections 1/4 NPT internal Mounting Configurations See figure 5 Approximate Weight 13.6 kg (30 lb) Top-Mounted Handwheel Specifications Operating Principle: Can be used for manual operation of the actuator or as an adjustable up travel stop Diameter: 171 mm (6.75 inches)
--	---

1. Use this value to determine the maximum torque output.

2. The pressure-temperature limits in this manual and any applicable code or standard should not be exceeded.

Description

The 1052 size 20 spring-and-diaphragm actuator is used on small rotary shaft valves and other equipment for throttling or on-off control applications. This actuator accepts a 3610J, 3620J, or PMV positioner, and a top-mounted handwheel is available for the unit.

The Style H mounting adaptation permits the actuator to be used with user-provided mounting brackets and couplings for rotary actuation of equipment other than Fisher valves. This mounting adaptation includes a flat-surface actuator mounting plate that is drilled and tapped for attaching the user-provided bracket. Cap screws for attaching the bracket are provided. The H mounting also includes an output shaft (with two milled flats) to provide the rotary output, either directly or through a user-provided coupling.

Dimensional information for the mounting plate and output shaft are shown in figure 4.

Specifications

Specifications are shown in table 1 for 1052, Size 20, Style H actuators. Some specifications for a given actuator as it originally comes from the factory are stamped on a nameplate attached to the actuator.

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.

To avoid personal injury or property damage caused by bursting of pressure retaining parts, do not apply pressure exceeding the Maximum Allowable Casing Pressure limit given in table 1 or on the nameplate. Use pressure limiting or pressure relieving devices to prevent the casing pressure from exceeding the maximum allowable casing pressure.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

NOTICE

To avoid parts damage, do not apply pressure that exceeds the Maximum Allowable Sizing Pressure (table 1) or produces a torque greater than the Maximum Allowable Output Torque (table 1) or the Maximum Allowable Valve Shaft Torque (see Catalog 14). Use pressure-limiting or pressure-relieving devices to prevent the diaphragm casing pressure from exceeding these limits.

A 1/4 NPT pressure connection is located on top of the actuator. Run either NPS 1/4 pipe or 3/8-inch tubing between the pressure connection and the instrument. Keep the length of tubing or pipe as short as possible to avoid transmission lag in the control signal. If a positioner is used, the pressure connection to the actuator is normally made at the factory.

When the actuator is completely installed and connected to the instrument, check it for correct action (air-to-open or air-to-close) to match the controlling instrument. For successful operation, the actuator rod and equipment operating shaft must move freely in response to the loading pressure change on the diaphragm.

Spring Compression Adjustment

Spring adjustment is shown in figure 2. Key numbers are shown in figure 6.

Initial Spring Compression

The 1052 nameplate specifies a SPRING INITIAL SET, which is the initial compression adjusted into the actuator spring. Initial compression is the casing pressure at which the diaphragm (key 3) and diaphragm rod (key 10) begin to move away from the up travel stop. The initial compression is selected (based upon the service conditions specified when the actuator was ordered) so that when the actuator is in service on the operated equipment, the equipment closes properly and full travel is obtained within a specified casing range.

If the actuator has been disassembled, or if the spring adjustment was changed, do NOT adjust the initial compression to exceed the SPRING INITIAL SET value on the nameplate.

Figure 2. Spring Adjustment

Proper bench set of the spring can only be made when the actuator “up” travel stop has been approximately adjusted. Insert a shaft in the actuator and adjust the “up” travel stop before establishing spring compression (since there is no travel stop in the upper diaphragm casing). Considerable error in adjustment is certain if the above procedure is not followed. This error can result in under travel of the actuator when the spring goes solid or excess compression has been applied.

Adjust the spring so that the diaphragm rod just starts to travel at the SPRING INITIAL SET pressure specified on the nameplate. To adjust the spring, remove the positioner, if one is used, or the cover. The lower part of the spring adjuster is notched, as shown in figure 2. Using a screwdriver as shown in figure 2, rotate the notches to the right to decrease spring compression or to the left to increase spring compression. Replace the positioner or the cover when adjustment is complete.

Stroking Range

The SPRING INITIAL SET listed on the nameplate is the optimum setting, and spring adjustments that cause this value to change or be exceeded are not recommended. For push-down-to-open action, the initial spring set is normally the maximum allowable to provide the maximum spring closing force. Any increase in this setting may overstress the spring at full travel. For push-down-to-close action, the initial spring set is the optimum balance between the air-to-close and spring-to-open breakout torque.

If, under operating conditions, the stroking range does not match the intended casing pressure, it may be possible to shift the stroking range by adjusting the spring to change the initial spring compression. A spring adjustment shifts the casing pressure span and equally increases (or decreases) the casing pressure at which the actuator begins to stroke and the pressure at which the actuator reaches full travel.

To adjust the spring, remove the positioner, if one is used, or the cover. The lower part of the spring adjuster is notched, as shown in figure 2. Using a screwdriver as shown in figure 2, rotate the notches to the right to shift the casing pressure span downward, or to the left to shift the casing pressure span upward. Replace the positioner or the cover.

Mounting Procedure

Use the following steps to connect the actuator to valve body or other equipment. Key numbers are shown in figure 6. Mounting dimensions are shown in figure 4.

Figure 3. Center of Gravity Dimensions

1488083-A

Note

Find dimensions and center of gravity information in figures 3 and 4 and the approximate weight in table 1. This information is required for fabrication of the proper bracket and coupling.

1. Attach an appropriate mounting bracket (not provided) to the mounting plate (key 22) in the desired orientation with the cap screws (key 78). See figure 4 for mounting dimensions on the mounting plate. Tighten the cap screws to the value in table 2.
2. Consult figure 5 for available mounting styles and positions. The actuator is normally positioned vertically with the valve or other equipment in a horizontal pipeline.

Note

If the milled flats on the end of the actuator output shaft (key 87) are oriented so that the output shaft cannot accommodate the operated equipment shaft, refer to the Changing Positions procedure of the Changing Actuator Mounting section. This procedure describes how the output shaft can be repositioned to accommodate the operated equipment shaft.

3. Slide the actuator (with the user-provided mounting bracket attached) into the user-provided coupling on the operated shaft. Then, secure the actuator to the operated equipment in the desired mounting position with appropriate fasteners, such as mounting cap screws. See figure 4 for output shaft dimensions.

Principle of Operation

Refer to figure 6. The diaphragm rod (key 10) moves down as loading pressure is increased on top of the diaphragm (key 3). As the loading pressure is decreased, the spring (key 11) forces the diaphragm rod upward.

The spring and diaphragm are selected to meet the requirements of the application and, in service, the actuator should produce full travel of the operated equipment with the diaphragm pressure as indicated on the nameplate.

Consult the positioner instruction manual for actuator principle of operation with positioner.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions. Key numbers referenced in the following steps are shown in figure 6.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Disassembly

The following procedure describes how the actuator can be completely disassembled. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job.

1. Isolate the operated equipment from its process. Release process pressure, vent all actuator loading pressure, and remove the tubing or pipe from the top of the actuator.
2. Remove the positioner, if applicable, or unscrew the machine screws (key 40) and remove the cover (key 39).
3. Rotate the handwheel (if one is used) counter-clockwise to be sure the handwheel is not compressing the spring (key 11).

⚠ WARNING

Be sure to relieve spring compression before loosening the diaphragm casing cap screws and nuts (keys 5 and 6). Personal injury can occur if spring compression forces the upper diaphragm casing (key 1) from the actuator.

Figure 4. Mounting Dimensions

19A1461_G

- To relieve spring compression, insert a screwdriver blade between the notches at the bottom of the spring adjuster (key 74) as shown in figure 2. Push the screwdriver tip to the right to rotate the adjuster until a stop is reached.
- Unscrew the cap screws (key 78) and remove the actuator from the operated equipment. Then, with the actuator at the top of its stroke, mark the orientation of the flats on the end of the output shaft (key 87) with respect to the actuator housing (key 20). Also, mark the orientation of the travel indicator (key 37) with respect to the travel indicator scale (key 35). These markings are used during reassembly to allow for proper output shaft positioning.
- Loosen the hex nut (key 145) to allow the output shaft (key 87) to slide out of the clamped lever (key 27).
- With the housing, output shaft, travel indicator, and travel indicator scale properly marked, unscrew the cap screws (key 23) and remove the mounting plate (key 22) and output shaft (key 87) assembly from the actuator housing. If necessary, remove the retaining ring (key 88) and separate the output shaft (key 87) from the mounting plate.
- Unscrew and remove the casing cap screws and hex nuts (keys 5 and 6) and the warning plate (key 56). Then, remove the upper diaphragm casing (key 1) and the diaphragm (key 3).
- Heat the cap screw (key 18) to 177°C (350°F) long enough for the thread locking adhesive (medium strength) (key 77) to lose its holding strength. Then, remove the cap screw (key 18). This separates the diaphragm rod/bearing

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

1052 Size 20 Actuator (H)

July 2023

Instruction Manual

D100323X012

assembly (key 10) from the lever (key 27). Remove the lever with the attached travel stops and hex nuts (keys 8 and 86).

10. Pull the diaphragm plate (key 4) and attached diaphragm rod (key 10) out of the actuator. Remove the cap screw (key 9) and washer (key 79) and separate the diaphragm plate and diaphragm rod.
11. Remove the actuator spring (key 11) from the actuator, lift out the spring adjuster (key 74), the spring seat (key 13), and the thrust washer (key 71).
12. Check the condition of the bearing (key 31). If replacement of the bearing is necessary, the travel indicator (key 37) must first be removed by removing the machine screws (key 38). Then, the hub (key 29) and travel indicator scale (key 35) must be removed by removing the self-tapping screws or cap screws (key 36). Mark the orientation of the travel indicator scale with respect to the actuator housing before removing it.

Assembly

This procedure assumes that the actuator is completely disassembled. If the actuator is not completely disassembled, start these instructions at the appropriate step. Key numbers referenced in the following procedure are shown in figure 6. Before assembling the actuator, apply lithium grease (key 76) to the threads of the spring adjuster (key 74), to the inside of the lever (key 27), and to the equipment operating shaft.

1. Replace the bearing (key 31) if it was removed. If necessary, install the travel indicator scale (key 35) with attached hub (key 29) and retaining ring (key 30) to the actuator housing (key 20) with the self-tapping screws or cap screws (key 36). When installing the travel indicator scale, make sure that the markings on the scale and housing that were made in step 10 of the Disassembly procedure are oriented correctly.

Table 2. Recommended Bolting Torques

DESCRIPTION KEY NUMBER	Bolt Size	TORQUE	
		Lbf•ft	N•m
Diaphragm Casing 5/6	3/8-24	20	27
Travel Stop 86	5/16-18	20	27
Diaphragm to rod 9	5/16-18	16	22
Rod end to lever 18	5/16-18	16	22
Housing to yoke 23	3/8-16	25	34
Clamped lever 28/145	5/16-18	20	27

2. If necessary, install the travel indicator (key 37) to the hub so that the markings on the travel indicator and travel indicator scale that were made in step 5 of the Disassembly procedure are oriented correctly. Attach the travel indicator to the hub with the machine screws (key 38).
3. If the diaphragm rod/bearing assembly (key 10) was removed from the actuator and separated, thread the rod into the rod end bearing.
4. Attach the diaphragm plate (key 4) to the diaphragm rod with the cap screw and washer (keys 9 and 79). Apply lithium grease (key 76) to the threads of the cap screw and to the portion of the rod that fits into the diaphragm plate.
5. Install the thrust washer (key 71), followed by the spring adjuster (key 74), the spring seat (key 13) and the spring (key 11) into the diaphragm housing.
6. Coat the threads of the cap screw (key 18) with thread locking adhesive (medium strength) (key 77).
7. Place the diaphragm plate, diaphragm rod and rod end bearing assembly into the actuator. Bolt the rod end bearing to the lever (key 27) with the cap screw (key 18).
8. Replace the diaphragm (key 3). Position the diaphragm casing (key 1) in place on the housing (key 20). Secure the diaphragm casing with cap screws and hex nuts (keys 5 and 6). Ensure that the warning plate (key 56) is replaced on the casing.
9. If necessary, assemble the lever using two travel stops studs (key 8) and locking nuts (key 86) for old and new style levers. Newer levers that can be clamped also require that you install the cap screw (key 28) and thread the lock nut (key 145) in place, but do not tighten it at this time.

10. Attach the output shaft (key 87) to the mounting plate (key 22) with the retaining ring (key 88). Then, with the actuator at the top of its stroke, attach the mounting plate and output shaft assembly to the actuator housing (key 20) with the cap screws (key 23) so that the markings that were made in step 5 of the Disassembly procedure are oriented correctly (output shaft to actuator housing and travel indicator to travel indicator scale).
11. For newer clamping levers, torque the cap screw and nut (keys 28 and 145) on the output shaft (key 87). See table 2 for torque values.
12. Adjust the initial spring compression as described in the spring compression adjustment procedure of the Installation section. Remember to replace the cover and cap screws (keys 39 and 40) after performing this procedure.
13. With the initial spring compression adjusted, slide the actuator onto the equipment operating shaft and secure it to the mounting bracket in the desired mounting position with mounting cap screws (key 78). Tighten the cap screws to the value in table 2.

Changing Actuator Mounting

The actuator is normally positioned vertically in a horizontal pipeline. However, each style can be mounted in two possible housing construction styles and four possible positions. See figure 5.

⚠ WARNING

Avoid personal injury from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the power actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Use the following procedures along with figure 6 for key number references to convert from style A to style B or vice versa or to change the mounting position.

Changing Styles

1. Perform steps 1 through 4 of the Disassembly portion of the Maintenance section.
2. Remove the self-tapping screws or cap screws (key 36), and then remove the hub with attached travel indicator (keys 29 and 37) and the travel indicator scale (key 35).
3. Unscrew the cap screws (key 78) and remove the actuator assembly from its mounting bracket.
4. Unscrew the cap screws (key 23) and remove the mounting plate (key 22) and output shaft (key 87) assembly from the actuator housing.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

1052 Size 20 Actuator (H)

July 2023

Instruction Manual

D100323X012

- Rotate the actuator housing 180 degrees while maintaining the appropriate position (1, 2, 3, or 4).

DESIRED ACTION OF		HOUSING CONSTRUCTION TO SPECIFY
Actuator	Valve Body or Other Equipment	
Push Down To Open ⁽¹⁾	Clockwise to Close ⁽³⁾	Style A
	Counterclockwise to Close ⁽³⁾	Style B
Push Down To Close ⁽²⁾	Clockwise to Close ⁽³⁾	Style B
	Counterclockwise to Close ⁽³⁾	Style A

1. This action uses the spring to close the valve or other equipment.
 2. This action uses the spring to open the valve or other equipment.
 3. When viewed from actuator side of valve or other equipment.

Figure 5. Actuator Housing Construction Styles and Mounting Positions

NOTES:

1

DOTTED LINES INDICATE ALTERNATE MOUNTING POSITIONS 2, 3, AND 4.

1488083-A

Note

In order to obtain a positive point of reference, position the actuator at the top of its stroke when performing the following two steps (steps 6 and 7).

- Position the lever (key 27) inside the actuator housing so that it is aligned with the holes at each end of the housing (key 20). Compare the position of the lever with the position shown in figure 2. Notice that when the lever is in the correct position to receive the output shaft, the down travel stop is nearly vertical.
- Before sliding the output shaft into the lever, make sure that the flats that are milled on the end of the output shaft are positioned appropriately. The flats may be positioned either parallel with or perpendicular to the spring barrel of the actuator housing when the actuator is at the top of its stroke. With the output shaft positioned appropriately, slide the output shaft and mounting plate assembly into the lever, and secure the mounting plate the the actuator housing with the cap screws (key 23). Tighten the cap screws to the value in table 2.
- Adjust the initial spring compression as described in the spring compression adjustment portion of the installation section.
- Secure the actuator housing in the desired position (1, 2, 3, or 4) to the mounting bracket with the cap screws (key 78). Tighten the cap screws to the torque in table 2.
- Separate the travel indicator (key 37) from the hub (key 29) by removing the machine screws (key 38). Slide the hub, with attached travel indicator scale (key 35), onto the splined output shaft so that the travel indicator screw holes align with the offset portion of the lever (where the diaphragm rod/bearing assembly (key 10) connects). With the hub positioned properly, the travel indicator can show the correct position of the operated equipment and can point in the direction of flow when the operated equipment is in the open position. Then, fasten the travel indicator to the hub with the machine screws (key 38), and fasten the travel indicator scale to the actuator housing

with the self-tapping screws or cap screws (key 36). When attaching the travel indicator scale, make certain that it is properly aligned with the travel indicator.

11. Replace the cover and machine screws (keys 40 and 39).

Changing Positions

1. Perform steps 1 through 4 of the Disassembly portion of the Maintenance section.
2. Unscrew the cap screws (key 78) and remove the actuator assembly from its mounting
3. Unscrew the cap screws (key 78) and remove the actuator assembly from its mounting bracket.
4. Mark the orientation of the output shaft (key 87) with respect to the actuator housing (key 20). This marking is used during re-assembly to allow for proper output shaft positioning. When the output shaft and housing are properly marked, unscrew the cap screws (key 23) and remove the mounting plate (key 22) and output shaft (key 87) assembly from the actuator housing.
5. Rotate the actuator housing (key 20) to the new position (1, 2, 3, or 4).
6. Position the lever inside the actuator housing so that it is aligned with the holes at each end of the housing. Compare the position of the lever with the position shown in figure 2. Notice that when the lever is in the correct position to receive the output shaft, the down travel stop is nearly vertical.
7. To install the output shaft into the lever, proceed as appropriate:
 - a. If the new actuator position is 90 degrees clockwise from the previous actuator position, align the output shaft so that its orientation mark is located 90 degrees counterclockwise from the mark on the actuator housing.
 - b. If the new actuator position is 90 degrees or 180 degrees counterclockwise from the previous position, align the output shaft so that its orientation mark is located either 90 degrees (for 90 degrees) or 180 degrees (for 180 degrees) clockwise (respectively) from the mark on the actuator housing.
8. Slide the output shaft and mounting plate assembly into the lever, and secure the mounting plate to the actuator housing with the cap screws (key 23). Tighten the cap screws to the torque in table 2.
9. Adjust the initial spring compression as described in the spring compression adjustment portion of the Installation section.
10. Secure the actuator housing to the mounting bracket with the cap screws (key 78). Tighten the cap screws to the torque in table 2.
11. Note the position of the valve body or other operated equipment and direction of rotation. Remove the machine screws (key 38) and position the travel indicator (key 37) accordingly. Replace the machine screws.
12. Replace the cover and machine screws (keys 40 and 39).

Top-Mounted Handwheel

Key numbers used in this section are shown in figure 7 except where indicated. The optional top-mounted handwheel, shown in figure 7, can be used as a manual actuator or as an adjustable up travel stop to limit full retraction of the diaphragm rod (key 10, figure 6).

The handwheel assembly is attached to a special upper diaphragm casing (key 1, figure 6) with cap screws (key 141). A hex nut (key 137) locks the handwheel in position.

Turning the handwheel (key 151) clockwise into the upper casing forces the pusher plate (key 135) against the diaphragm and diaphragm plate (keys 3 and 4, figure 6) to compress the spring (key 11, figure 6) and move the diaphragm rod downward. Turning the handwheel counterclockwise allows the actuator spring to move the diaphragm rod upward. If the action is push-down-to-close, full opening of the operated equipment can be restricted

by positioning the handwheel at the desired position. If the action is push-down-to-open, full closing of the operated equipment can be restricted by use of the handwheel.

Instructions are given below for complete disassembly and assembly required for inspection and parts replacement.

Disassembly

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1, figure 4) away from the actuator, relieve spring compression before diaphragm casing bolting is loosened.

1. Remove the upper diaphragm casing (key 1, figure 6) by following steps 1 through 4, and 6 of the Disassembly portion of the Maintenance section.
2. Remove the cotter pin, hex nut, handwheel, and hex nut (keys 247, 54, 51, and 137). Unscrew the stem (key 133) out through the actuator end of the handwheel body (key 142).
3. Remove the cap screws (key 141), and separate the handwheel assembly from the upper casing.
4. Check the condition of the O-rings (keys 138 and 139); replace them if necessary.
5. If it is necessary to remove the pusher plate (key 135), drive out the groove pin (key 140).

Assembly

1. Before assembling, lubricate the threads of the stem (key 133) and the bearing surfaces of the stem and pusher plate (key 135) with lithium grease (key 241).
2. If the pusher plate was removed, re-attach it to the stem, and drive in a new groove pin (key 140).
3. Apply lithium grease (key 241) to the O-rings (keys 138 and 139). With the O-rings in place, thread the stem into the handwheel assembly.
4. Attach the handwheel assembly to the upper diaphragm casing (key 1, figure 6) with cap screws (key 141).
5. Install the hex nut, handwheel, hex nut, and cotter pin (keys 137, 51, and 247).
6. Install the diaphragm casing, making certain the warning tag is in place on the casing flange.
7. Tighten the cap screws (key 5, figure 6) evenly in a criss-cross pattern to the torque shown in table 2.
8. Adjust the initial spring compression as described in the Spring Compression Adjustment section.

Parts Ordering

Each actuator has a nameplate attached to the actuator housing and a serial number stamped on it. Always refer to this serial number when corresponding with your [Emerson sales office](#) regarding replacement parts or technical information.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

W5030

Introduction

Scope of Manual

This instruction manual includes installation, adjustment, operation, maintenance, and parts information for the 1052, size 20, Style F and G diaphragm rotary actuator (figure 1), and the optional top-mounted handwheel (figure 4). Instructions for the control valve, rotary positioners, and accessories are included in separate manuals.

Do not install, operate, or maintain a 1052 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

The spring-and-diaphragm actuator is used on small rotary shaft valves for throttling or on-off applications. It mounts to V150 Vee-Ball™ valves, V500 valves, eccentric disk valves, and butterfly valves with 3/8 inch and 1/2 inch splined shafts. The actuator accepts a 3610J, 3620J, or PMV positioner. A top-mounted handwheel is available for the unit.

Specifications

Specifications are shown in table 1 for 1052 Style F & G size 20 actuators. Some specifications for a given actuator, as it originally comes from the factory, are shown on the nameplate attached to the actuator.

Table 1. Specifications

Operating Principle Direct Acting: Increasing loading pressure forces the diaphragm rod from the top to the bottom of the casing Casing Pressure Ranges ■ 0 to 1.2 bar (0 to 18 psig), ■ 0 to 2.3 bar (0 to 33 psig), or ■ 0 to 2.8 bar (0 to 40 psig) depending on spring used Maximum Allowable Sizing Pressure⁽¹⁾ 3.5 bar (50 psig) Maximum Allowable Casing Pressure⁽²⁾ 4.1 bar (60 psig) Maximum Rotation 90 degrees (travel is adjustable between 60 degrees and 90 degrees by travel stops) Acceptable Valve Shaft Diameters, Inches ■ 9.5 mm (3/8 inch) or ■ 12.7 mm (1/2 inch)	Stroking Time Depends on rotation, spring rate, initial spring compression, and supply pressure. If stroking time is critical, consult your Emerson Automation Solutions sales office Material Temperature Capabilities⁽²⁾ –40 to 82°C (–40 to +180°F) Pressure Connections 1/4 NPT internal Mounting Configurations See figures 2 and 3 Approximate Weight 13.6 kg (30 lb) Top-Mounted Handwheel Specifications Operating Principle: Can be used for manual operation of the actuator or as an adjustable “up” travel stop Diameter: 121 mm (6.75 inch)
---	---

1. Use this value to determine the maximum torque output.

2. The pressure-temperature limits in this manual and any applicable code or standard should not be exceeded.

Principle of Operation

Key numbers refer to figure 5. The diaphragm rod (key 10) moves down as loading pressure is increased on top of the diaphragm (key 3). As the loading pressure is decreased, the spring (key 11) forces the diaphragm rod upward.

The spring and diaphragm are selected to meet the requirements of the application and, in service, the actuator should produce full travel of the valve with the diaphragm pressure as indicated on the nameplate.

Consult the positioner instruction manual for actuator principle of operation with positioner.

Installation

WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

To avoid personal injury or property damage caused by bursting of pressure retaining parts, do not apply pressure exceeding the Maximum Allowable Casing Pressure limit given in table 1 or on the nameplate. Use pressure limiting or pressure relieving devices to prevent the casing pressure from exceeding the maximum allowable casing pressure.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

NOTICE

To avoid parts damage, do not apply pressure that exceeds the Maximum Allowable Sizing Pressure (table 1) or produces a torque greater than the Maximum Allowable Valve Shaft Torque (see Catalog 14). Use pressure-limiting or pressure-relieving devices to prevent the diaphragm casing pressure from exceeding these limits.

The actuator, as it comes from the factory, is normally mounted on a valve. Follow valve instructions when installing the control valve in the pipeline.

A 1/4 NPT pressure connection is located on top of the actuator. Run either 1/4 NPT pipe or 3/8 inch tubing between the pressure connection and the instrument. Keep the length of tubing or pipe as short as possible to avoid transmission lag in the control signal. If a valve positioner is used, the pressure connection to the actuator will normally be made at the factory.

When the control valve is completely installed and connected to the actuator, check it for correct action (air-to-open or air-to-close) to match the controlling instrument. For successful operation, the actuator stem and valve shaft must move freely in response to the loading pressure change on the diaphragm.

Use the following steps to connect a valve and an actuator that have been ordered separately. Because the procedures in the Mounting Procedure section require removal of initial spring compression, it is necessary to read the Adjusting Spring Compression section before completing the installation.

Mounting Procedure

This procedure assumes that the style ordered from the factory (A, B, C or D) was correct. Key numbers refer to figure 5.

1. Remove the positioner if one is used, and unscrew machine screws (key 40) to remove the positioner bracket or the cover (key 39).
2. Consult figure 2 for available mounting styles and positions. The actuator is normally mounted vertically with the valve in a horizontal pipe run.
3. Ensure all the initial spring compression has been removed from the spring. To relieve spring compression, insert a screwdriver blade between the notches at the base of the spring adjusting screw (key 74) as shown in figure 3. Push the tip of the screwdriver blade to the right. This rotates the spring adjusting screw counterclockwise. Continue until the stop is reached which occurs when the spring seat (key 13) is lowered to the adjusting screw base.
4. Before sliding the valve shaft into the lever, position the valve as follows:
 - For push-down-to-close action, the valve should be fully open.
 - For push-down-to-open action, the valve should be fully closed (see the valve instruction manual).
5. Position the lever in the housing to align with the holes at each end of the housing. Compare the position of the lever to the position shown in figure 2. Notice that when the lever is in the correct position to receive the valve shaft, the "down" travel stop is nearly vertical, as shown in figures 3 and 5.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

1052 Size 20 Actuator (F & G)

July 2023

Instruction Manual

D100322X012

MOUNTING	ACTION ⁽¹⁾	VALVE SERIES OR DESIGN				VALVE SERIES OR DESIGN

1. PDTC—Push-down-to-close, and PDTO—Push-down-to-open.
2. A left hand ball will be required for the NPS 3 through 12 Series B and the NPS 14 to 20, with or without attenuator.
3. CCW—Counterclockwise, and CW—Clockwise.

Figure 2. Mounting Styles and Positions

- Slide the valve shaft into the lever. Insert the lever in the opening. Tighten the valve mounting cap screws (see table 2).
- Remove machine screws (key 36) and remove the hub (key 29) and the travel indicator scale (key 35).
- Reposition the hub on the splined valve shaft so that the travel indicator screw holes align with the offset portion (where the rod end bearing connects) of the lever.
- Loosen the hex nut (key 145) to allow the valve shaft to slide out of the clamped lever (key 27).
- Center the lever in the opening. For newer clamping levers, torque the cap screw and nut (keys 28 and 145) to a torque listed in table 2.
- With the hub positioned properly, the travel scale and indicator can show the correct position of the valve and point in the direction of flow when the valve is open. Replace the machine screws, fastening the travel indicator scale to the housing and the travel indicator to the hub.

12. Adjust the "up" travel stop (key 8) so that it touches the housing, and then lock the travel stop in position with the hex nut (key 86).

Figure 3. Spring Adjustment

⚠ WARNING

To avoid personal injury and equipment damage from moving parts within the actuator, keep fingers and tools away from the actuator when stroking the valve with the actuator cover removed.

13. Fully stroke the valve, and adjust the "down" travel stop so that it touches the housing. Then lock the travel stop in position with the hex nut (key 86).

Adjusting Spring Compression

Spring adjustment is shown in figure 3. Key numbers are shown in figure 5.

Initial Compression

NOTICE

To avoid adjustment error which could lead to possible product damage, comply with the following bench set adjustment procedure.

The 1052 nameplate specifies a Spring Initial Set, which is the initial compression adjusted into the actuator spring. Initial compression is the casing pressure at which the diaphragm (key 3) and diaphragm rod (key 10) begin to move away from the "up" travel stop. The initial compression was selected (based upon the service conditions specified when the actuator was ordered) so that when the actuator and valve are in service, the valve will seat properly and full travel will be obtained within a standard casing range of 0 to 1.2 bar (0 to 18 psig) or 0 to 2.3 bar (0 to 33 psig).

If the actuator has been disassembled or if the spring adjustment was changed, the initial compression may be adjusted to not exceed the Spring Initial Set value on the nameplate.

Proper bench set of the spring can only be made when the actuator "up" travel stop has been approximately adjusted. Insert a shaft in the actuator and adjust the "up" travel stop before establishing spring compression (since there is no travel stop in the upper diaphragm casing). Considerable error in adjustment is certain if the above procedure is not followed. This error can result in under travel of the actuator when the spring goes solid or excess spring compression has been applied.

Adjust the spring so that the diaphragm rod just starts to travel at the Spring Initial Set pressure specified on the nameplate. To adjust the spring, remove the positioner, if one is used, or the cover. The lower part of the spring adjusting screw is notched, as shown in figure 3. Using a screwdriver as shown in figure 3, rotate the notches to the right to decrease spring compression or to the left to increase spring compression. Replace the positioner or the cover.

Stroking Range

If, under operating conditions, the stroking range does not match the intended casing pressure, it may be possible to shift the stroking range by making a spring adjustment to change the initial spring compression. A spring adjustment will shift the casing pressure span and will equally increase (or decrease) the casing pressure at which the actuator begins to stroke and the pressure at which the actuator reaches full travel.

To adjust the spring, remove the positioner, if one is used, or the cover. The lower part of the spring adjusting screw is notched. Using a screwdriver as shown in figure 3, rotate the notches to the right to shift the casing pressure span downward, or to the left to shift the casing pressure span upward. Replace the positioner or the cover.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions. Instructions are given below for disassembly and assembly of parts. Key numbers are shown in figure 5, unless otherwise noted.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you are working on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Table 2. Recommended Bolting Torques

DESCRIPTION KEY NUMBER	TORQUE		
	Sizes	N•m	Lbf•ft
Casing Diaphragm 5/6	3/8-24	27	20
Diaphragm to rod 9	5/16-18	22	16
Rod end to lever 18	5/16-18	22	16
To Yoke 23	3/8-16	34	25
Travel Stop nut 86	5/16-18	27	20
Clamped lever 145/28	5/16-18	27	20

Disassembly

The following procedure describes how the actuator can be completely disassembled. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job.

1. Isolate the operating equipment from its process. Release process pressure, vent all actuator loading pressure, and remove the tubing or pipe from the top of the actuator.
2. Remove positioner, if applicable, or remove the machine screws (key 40) and remove the cover (key 39).
3. Rotate the handwheel (if one is used) counterclockwise to be sure the handwheel is not compressing the spring (key 11).

⚠ WARNING

Be sure to relieve spring compression before loosening the diaphragm casing cap screws and nuts (keys 5 and 6). Personal injury can occur if spring compression forces the upper diaphragm casing (key 1) from the actuator.

4. To relieve spring compression, insert a screwdriver blade between the notches at the bottom of the spring adjusting screw (key 74) as shown in figure 3. Push the screwdriver tip to the right to rotate the adjusting screw until a stop is reached.
5. Loosen the hex nut (key 145) to allow the valve shaft to slide out of the clamped lever (key 27).
6. Remove the valve mounting cap screws. Slide the valve shaft out of the lever.
7. Unscrew and remove casing cap screws and nuts (keys 5 and 6). Remove the upper casing and the diaphragm (key 3).
8. Heat the cap screw (key 18) to 177°C (350°F) long enough for the medium strength thread-locking compound (key 77) to lose its holding strength. Then, remove the cap screw (key 18). This separates the actuator rod and rod end bearing from the lever.
9. Pull the diaphragm plate (key 4) and attached diaphragm rod out of the actuator. Remove the cap screw (key 9) to separate the diaphragm plate and diaphragm rod.
10. Remove the actuator spring (key 11) from the actuator, lift out the spring adjusting screw (key 74), the spring seat (key 13), and the thrust washer (key 71).
11. Check the condition of the bearing (key 31). If replacement of the bearing is necessary, the travel indicator (key 37) must first be removed by removing the machine screws (key 38). Then, the hub (key 29) and travel indicator scale (key 35) must be removed by removing the self-tapping screws or cap screws (key 36). Mark the orientation of the travel indicator scale with respect to the actuator housing before removing it.

Assembly

This procedure assumes that the actuator was completely disassembled. If not, start these instructions at the appropriate step. Key numbers are shown in figure 5. Use bolt torques in table 2. Before assembly, apply lithium grease to the threads of the spring adjusting screw (key 74), to the inside of the lever (key 27), and to the valve shaft.

1. Replace the bushing (key 31) if it was removed.
2. If the diaphragm rod/bearing assembly (key 10) was removed from the actuator and separated from each other, thread the rod into the bearing.
3. Bolt the rod end bearing to the lever (key 27) with cap screw (key 18). Coat the threads of the cap screw with medium strength thread-locking compound.
4. If necessary, assemble the lever using two travel stop studs (key 8) and locking nuts (key 86) for old and new style levers. Newer levers are clamped, and will also require that you install the cap screw (key 28) and thread the lock nut (key 145) in place, but do not tighten it at this time.
5. Place the lever, rod end bearing, and diaphragm rod into the actuator with the diaphragm rod inside the diaphragm housing (key 20).
6. Install the thrust washer (key 71), followed by the spring adjusting screw (key 74), the spring seat (key 13), and the spring (key 11) into the diaphragm housing.
7. Attach the diaphragm plate (key 4) to the diaphragm rod with cap screw (key 9) and washer (key 79). Apply lithium grease (key 76) to the portion of the rod that fits into the diaphragm plate.
8. Replace the diaphragm (key 3). Position the diaphragm casing (key 1) in place on the diaphragm housing (key 20). Secure the diaphragm casing with cap screws and nuts (keys 5 and 6). Ensure that the warning plate (key 56) is replaced on the casing.
9. Attach the valve to the actuator, and position the travel indicator as described in the Mounting Procedure section.
10. Adjust the initial spring compression as described in the Adjusting Spring Compression section.

Changing Actuator Mounting

The actuator is normally positioned vertically in a horizontal pipeline. However, each style can be mounted in four possible mounting styles and four possible positions. See figure 2.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Always wear protective gloves, clothing and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you are working on the equipment.
- The valve box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Style A is right-hand mounted while style D is left-hand mounted. In all other ways the styles A and D are identical.

Style B is right-hand mounted while style C is left-hand mounted. In all other ways the styles B and C are identical.

Use the following procedure to convert from styles A and D to styles B and C (or vice versa) or to change the mounting position.

1. Follow steps 1 through 6 in the Disassembly portion of the Maintenance section.
2. If changing styles,
 - a. Unscrew cap screws (key 23), and remove the actuator housing (key 20) from the mounting yoke (key 22).
 - b. Rotate the housing 180 degrees, maintaining the appropriate position (1, 2, 3, 4), and place the actuator onto the mounting yoke.
3. If changing position, unscrew cap screw (key 23), and rotate the actuator housing to the desired position. Consult table 2 for appropriate bolt torques.
4. Secure actuator housing (key 20) to the mounting yoke (key 22) with cap screws (key 23). Consult table 2 for appropriate bolt torques.
5. Follow steps in the Mounting Procedure section to connect the actuator to the valve.
6. Adjust initial spring compression as described in the Adjusting Spring Compression section.

Top-Mounted Handwheel

Key numbers used in this section are shown in figure 4 except where indicated.

The optional top-mounted handwheel, shown in figure 4, can be used as a manual actuator or as an adjustable "up" travel stop to limit full retraction of the diaphragm rod (key 10, figure 5).

The handwheel assembly is attached to a special upper diaphragm casing (key 1, figure 5) with cap screws (key 141). A hex nut (key 137) locks the handwheel in position.

Turning the handwheel (key 51) clockwise into the upper casing forces the pusher plate (key 135) against the diaphragm and diaphragm plate (keys 3 and 4, figure 5) to compress the spring (key 11, figure 5) and move the diaphragm rod downward. Turning the handwheel counterclockwise allows the actuator spring to move the diaphragm rod upward. If the valve is "push-down-to-close", full opening can be restricted by positioning the handwheel at the desired position. If the valve is "push-down-to-open", full closing of the valve can be restricted by using the handwheel.

Instructions are given below for complete disassembly and assembly required for inspection and parts replacement.

Disassembly

WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing (key 1, figure 5) away from the actuator, relieve spring compression before diaphragm casing bolting is loosened.

1. Remove the upper diaphragm casing (key 1, figure 5) by following steps 1 through 5, and 7 of the Disassembly part of the Maintenance section.
2. Remove the cotter pin, hex nut, handwheel, and locknut (keys 247, 54, 51, and 137). Unscrew the stem (key 133) out through the actuator end of the handwheel body (key 142).

3. Remove cap screws (key 141), and separate the handwheel assembly from the upper casing.
4. Check the condition of the O-rings (keys 138 and 139); replace them if necessary.
5. If it is necessary to remove the pusher plate (key 135), drive out the groove pin (key 140).

Assembly

1. Before assembling the actuator, lubricate the thread of the stem (key 133) and the bearing surfaces of the stem and pusher plate (key 135) with lithium grease.
2. If the pusher plate was removed, re-attach it to the stem, and drive in a new groove pin (key 140).
3. Apply lithium grease (key 241) to the O-rings (keys 138 and 139). With the O-rings in place, thread the stem into the handwheel assembly.
4. Attach the handwheel assembly to the upper diaphragm casing (key 1, figure 5) with cap screws (key 141).
5. Re-install the locknut, handwheel, hex nut, and cotter pin (keys 137, 51, 54, and 247).
6. Re-install the diaphragm casing, making certain the warning tag is in place on the casing flange.
7. Tighten the cap screws (key 5, figure 5) evenly in a criss-cross pattern to the torque shown in table 2.
8. Adjust the initial spring compression as described in the Adjusting Spring Compression section.

Parts Ordering

Each actuator has a nameplate attached to the actuator housing and a serial number stamped on it. Always refer to this serial number when corresponding with your [Emerson sales office](#) regarding replacement parts or technical information.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

Scope of Manual

This instruction manual includes installation, adjustment, maintenance, and parts ordering information for the Fisher 1052 (Size 70) pneumatic piston rotary actuator (see figure 1).

This instruction manual also provides information for the optional top-mounted handwheel, up and down travel stops, locking mechanism, and pipe-away vent.

Table 1. 1052 Actuator Specifications

Operation Direct Acting: Increasing loading pressure extends the diaphragm rod out of the spring barrel Service: For on-off or throttling service with or without a positioner Actuator Sizes 70 Maximum Diaphragm Sizing Pressure⁽¹⁾ 3.8 bar (55 psig) Maximum Diaphragm Casing Pressure⁽³⁾ 4.5 bar (65 psig) Maximum Valve Shaft Rotation Standard: 90 degrees rotation travel stop Optional: 60 or 75 degrees rotation travel stop Valve Shaft Diameters, mm (Inches) ■ 31.8 (1-1/4), ■ 38.1 (1-1/2), ■ 44.5 (1-3/4), or ■ 50.8 (2) Stroking Time Dependent on actuator size, rotation, spring rate, initial spring compression, and supply pressure. Approximate Weights See table 2. Additional Specifications For casing pressure ranges and for material identification of the parts, see the Parts List
--	--

1. Use this value to determine the maximum torque output allowed.

2. The pressure/temperature limits in this manual and any applicable standard or code limitation for valve should not be exceeded.

3. This maximum casing pressure is not to be used for normal operating pressure. Its purpose is to allow for typical regulator supply settings and/or relief valve tolerances.

Instructions for the control valve, positioner, accessories, and other sizes of actuators are covered in separate instruction manuals.

Top-Mounted handwheels can be applied for infrequent service as a manual handwheel actuator. Also, an adjustable up travel stop can be added to the actuator to limit its stroke in the upward direction, or an adjustable down travel stop can be added to limit actuator stroke in the downward direction.

Do not install, operate, or maintain a 1052 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

Figure 2. Typical 1052 Actuator Adjustable Spring Seat

Description

1052 diaphragm rotary actuators are pneumatic spring-return actuators for use with rotary-shaft control valves. It can be used for on-off service, or it can be used for throttling service when equipped with or without a valve positioner. The 1052 actuator spring is adjustable (see figure 2).

Table 2. Approximate Actuator Weights

SIZE	1052		TOP-MOUNTED HANDWHEEL	
	Kg	Lb	Kg	Lb
70	123	272	21	47

Specifications

Specifications are shown in table 1. Specifications for actuator operation, as it originally comes from the factory, are stamped on the nameplate attached to the actuator.

Educational Services

For information on available courses for Fisher 1052 size 70 rotary actuators, as well as a variety of other products, contact:

Emerson Automation Solutions

Installation

When an actuator and valve body are shipped together, the actuator is normally mounted on the valve. Follow the valve body instructions when installing the control valve in the pipeline, and then perform the procedures presented in the Loading Connection section. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the procedures presented in the Actuator Mounting section. And, if the actuator requires a pipe-away vent, or if a retrofit pipe-away kit needs to be installed, refer to the Pipe-Away Vent section.

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations. Be aware of pinching parts during installation operations.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

1052 Size 70 Actuators

June 2017

Instruction Manual

D104083X012

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

Table 3. Recommended Bolting Torques

Description, Key Number	Size	N•m	lbf•ft

Side of housing, 34 4200/PMV	1/2-13	81	60
Handwheel top, 54	---	34	25
Diaphragm head to rod/Adjustable down travel stop, 54	3/4-16	69	51
Rod end to turnbuckle, 58	7/8-14-LH	163	120
Handwheel to actuator, 141	1/2-13	81	60

CAUTION

To avoid parts damage, do not use an operating pressure that exceeds the Maximum Diaphragm Casing Pressure (table 1) or produces a torque greater than the Maximum Allowable Valve Shaft Torque. Use pressure-limiting or pressure-relieving devices to prevent the diaphragm casing pressure from exceeding its limit.

To avoid parts damage, do not stroke the actuator while cover (key 33) is off.

Actuator Mounting

Use the following steps to connect a valve and an actuator. Key numbers are shown in figure 8.

⚠ WARNING

To avoid personal injury, perform the steps in the WARNING at the beginning of the Maintenance section to isolate the control valve and actuator.

1. Unscrew cap screws and washers (keys 34 and 63), and remove the cover (key 33).
2. Refer to figure 3 for available mounting styles and positions. When mounting on a Vee-Ball V150, V200 or V300 valve, check the valve manual to determine if it is Series B. The actuator is normally positioned vertically with the valve in a horizontal pipeline (see figure 3).

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

Left-Hand	PDTC	CCW	NA	D	D	CW	C	C
	PDTO	CCW	NA	C	C	CW	D	D
Left-Hand (Optional) ⁽²⁾	PDTC	CW ⁽⁴⁾	NA	C	NA	NA	NA	NA
	PDTO	CW	NA	D	NA	NA	NA	NA

1. PDTC—Push-down-to-close, and PDTO—Push-down-to-open.
 2. A left hand ball will be required for the NPS 3 through 12 Series B and the NPS 14 to 20, with or without attenuator.
 3. CCW = counterclockwise
 4. CW = clockwise

⚠ WARNING

To avoid personal injury or property damage, the 1052 size 70 actuator, due to its weight, must be externally supported if mounted in the horizontal position.

- When mounting the actuators, make sure that the bushing (key 67) and valve shaft are in-line so that the bushing will slide onto the valve shaft without damage.
- Mount the actuator on the valve body and secure it with the valve mounting screws. The torque for 1/2 to 1-inch shafts is 88 N•m (65 lbf•ft); for 1-1/4 to 1-1/2 inch shafts is 136 N•m (100 lbf•ft); for 1-3/4 to 2-inch shafts is 183 N•m (135 lbf•ft).

CAUTION

Exceeding any torque requirement may impair the safe operation of this actuator by causing broken or damaged parts. Refer to table 3 for the bolting torque requirements.

- Screw the left-hand threaded locknut (key 58) onto the diaphragm rod (key 10) as far as possible.
- Screw the turnbuckle (key 57) as far as it will go onto the actuator rod.
- Screw the locknut (key 16) as far as it will go onto the rod end bearing (key 17). Thread this assembly completely into the turnbuckle (key 57).
- If the lever (key 27) is attached to the rod end bearing, remove the cap screw and hex nut (keys 18 and 19).
- If the 1052 spring adjustment has been changed, complete the Initial Setting portion of the 1052 Spring Adjustment section before proceeding.
- Consult the appropriate valve instruction manual's Installation section for lever/valve shaft orientation marks, and slide the lever into place (see figure 4). Clamp with the cap screw (key 28).
- Rotate the lever (key 27) to align with the rod end bearing (key 17). This connection can be aided by moving the actuator off its up travel stop with a regulated air source and adjusting the turnbuckle (key 57) slightly.
- Apply sealant (key 77) or equivalent thread-locking compound to the threads of the cap screw (key 18).
- Connect the lever (key 27) and the rod end bearing (key 17) with the cap screw and hex nut (keys 18 and 19). Tighten the cap screw to the recommended bolt torque shown in table 3.
- Note the valve position and direction of rotation. Position the travel indicator (key 37) accordingly.
 - If no handwheel actuator is to be used, position the travel indicator (key 37) according to the valve position just noted. Replace the cover (key 33), and secure with washers and cap screws (keys 34 and 63). If holes in the cover and housing (key 20) do not align, temporarily loosen the cap screws (key 23), and shift the housing slightly.

Figure 3. Mounting Styles and Positions for the 1052 Actuator

CAUTION

To avoid parts damage, do not stroke the actuator while the cover (key 33) is off.

- b. If a manual handwheel actuator is to be used, refer to the separate handwheel actuator instruction manual for mounting instructions.
15. Replace the cover (key 33), and secure with cap screws and washers (keys 34 and 63). If the holes in the cover and housing (key 20) do not align, use a regulated air source to move the actuator slightly off the up travel stop. If the hole alignment cannot be obtained in this manner, temporarily loosen the cap screws (key 23), and shift the housing slightly.

Figure 4. Lever Operating Clearance

CAUTION

To avoid parts damage, do not stroke the actuator while the cover (key 33) is off.

- Follow the instructions given in the Turnbuckle Adjustment section before proceeding to the Loading Connection section.

Valve Flow Direction

Valve construction can change the flow direction for a control valve assembly. It is important to observe the flow direction in all valve applications **before** installing the valve in the pipeline (see figure 3). Refer to the appropriate valve bulletin or instruction manual.

Note

Observe all warnings and cautions provided in the appropriate valve instruction manual Installation section.

Loading Connection

- Connect the loading pressure piping to the pressure connection in the top of the diaphragm casing. Run either pipe or tubing between the pressure connection and the instrument. If necessary, remove the 1/4 inch bushing in the pressure connection to increase connection size.

- Keep the length of pipe or tubing as short as possible to avoid transmission lag in the control signal. If an accessory (such as a volume booster or a valve positioner) is used, be sure that the accessory is properly connected to the actuator. If a valve positioner is part of the assembly, the pressure connection to the actuator will normally be made at the factory.

Table 4. Wrench Size Required for Turnbuckle Adjustment, Inches

ACTUATOR		TURNBUCKLE (KEY 57)	LOWER LOCKNUT (KEY 16)	UPPER LOCKNUT (KEY 58)
Type	Size			
1052	70	1-5/16	1-1/8	1-5/16

- When the control valve is completely installed and connected to the instrument, check for correct action (air-to-open or air-to-close) to match the controlling instrument. For successful operation, the actuator stem and valve shaft must move freely in response to the loading pressure change on the diaphragm.

Adjustment

Turnbuckle Adjustment

Correct turnbuckle adjustment ensures that the valve is correctly closed when the actuator is against its travel stops. Key numbers are shown in figure 8.

For accurate adjustment to the zero-degree valve disk or ball position, remove the valve from the pipeline. Refer to the valve instruction manual for instructions.

A regulated air supply will be required to stroke the actuator. Refer to table 4 for the sizes of the three open-end wrenches required for this procedure.

- Remove the access plate (key 59). Also remove the machine screws (key 60), if present.

Note

For the most accurate adjustment of the actuator, do not remove the cover (key 33) during this procedure.

- Loosen the lower locknut (key 16).
- Make sure the actuator housing (key 20) is clear of any tools or other instruments that could obstruct the actuator stroke path. Pressure the diaphragm casing enough to stroke the actuator down so that the left-hand threaded upper locknut (key 58) is accessible through the access opening. Loosen the locknut.
- Consult the appropriate valve instruction manual for determining the closed position of the valve. Then use one of the following:
 - Push-down-to-close**—Slowly stroke the actuator to the down travel stop. Adjust the turnbuckle (key 57) until the valve is in the closed position. Lock this adjustment with the left-hand threaded locknut (key 58). Stroke the actuator to the mid-travel position, and tighten the locknut (key 16).
 - Push-down-to-open**—Release all pressure from the diaphragm casing, making sure the diaphragm is against its up travel stop. Be sure that the optional handwheel is adjusted to its topmost position so that the zero position of the actuator and valve can be reached simultaneously. Check the valve position. Stroke the actuator so the turnbuckle (key 57) is accessible through the access opening. Adjust the linkage. Release pressure to the actuator, and check the new adjustment. Continue this procedure until the valve is in the closed position when the actuator is resting on its up travel stop. Stroke the actuator to the mid-travel position, and tighten the locknut (key 16). Stroke the actuator, and tighten the left-hand threaded locknut (key 58).

5. Replace the access plate (key 59).
6. Loosen the self-tapping screws (key 38), adjust the travel indicator (key 37), and re-tighten the self-tapping screws.

1052 Spring Adjustment

Initial Setting

The 1052 nameplate specifies an initial spring setting, which is the initial setting adjusted into the actuator spring. Initial setting is the casing pressure at which the diaphragm and diaphragm rod begin to move away from the up travel stop **with the actuator disconnected from the valve**. (With the actuator connected to the valve and pressure applied to the valve, a higher pressure will be required to start actuator travel).

The initial setting was selected (based upon the service conditions specified when the actuator was ordered) so that, when the actuator and valve are in service, the valve will seat properly and full travel will be obtained within a diaphragm casing range of 0 to 2.3, 0 to 2.8, or 0 to 3.8 bar (0 to 33, 0 to 40, or 0 to 55 psig) depending on specific actuator size and construction.

If the actuator has been disassembled or if the spring adjustment was changed, and it is desired to match the initial setting stated on the nameplate, make sure the rod end bearing (key 17, figure 8) has been disconnected from the lever (key 27, figure 8). Adjust the spring so that the diaphragm rod just starts to travel at the spring set pressure specified on the nameplate.

Be sure the rod end bearing does not hit the lever as the diaphragm and diaphragm rod move away from the up travel stop. To adjust the spring, insert a round rod into one of the holes in the lower bearing seat (key 73, figure 8). Hole diameter is 19.1 mm (3/4 inch) for size 70 actuators. Rotate the bearing seat to move it toward the casing to increase initial setting or away from the casing to decrease initial setting (keys 1 and 2, figure 8).

Stroking Range

The initial spring setting listed on the nameplate has been determined to be the optimum setting, and it is not recommended to make spring adjustments that will cause this value to change or be exceeded. For push-down-to-open valve action, the initial spring setting is the maximum allowable to provide the maximum spring closing force.

CAUTION

Any increase of this setting will over-stress the spring at full travel and may shorten the fatigue life of the spring.

For push-down-to-close valve action, the initial spring set has been determined to be the optimum balance between the air-to-close and the spring-to-open breakout torque.

If the 1052 actuator is to be changed from one valve action to another (i.e., push-down-to-close to push-down-to-open), first, refer to the table for key 11 in the Parts List section to determine the proper initial spring setting; then, adjust the unit according to the procedures in the Initial Settings portion of the 1052 Spring Adjustment section.

Principle of Operation

The diaphragm rod moves down as loading pressure is increased on top of the diaphragm. As the loading pressure is decreased, the spring forces the diaphragm rod upward.

The spring and diaphragm have been selected to meet the requirements of the application and, in service, the actuator should produce full travel of the valve with the diaphragm pressure as indicated on the nameplate.

Consult the separate positioner instruction manual for actuator principle of operation with positioner.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions. Key numbers are shown in figure 8.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury. Be aware of pinching parts during maintenance operations.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

CAUTION

To avoid parts damage, do not stroke the actuator while cover (key 33) is off.

Disassembly

The following procedure describes how to completely disassemble the actuator. When inspecting and replacing parts, perform only those steps necessary to accomplish the repair.

Do not, under ordinary circumstances, remove the cap screws (keys 7, 8, and 21) at this time.

CAUTION

Cap screw (key 18) must be disengaged from the lever (key 27) before removing the diaphragm casing (key 1). Failure to do so will allow the spring precompression to rotate the valve beyond its fully open or closed position. This could cause damage to the valve components and/or seal.

1. Perform the steps in the **WARNING** at the beginning of the Maintenance section to isolate the control valve and actuator.
2. Remove the tubing or piping from the top of the actuator.
3. Remove the positioner, if used. If necessary, refer to the positioner instruction manual for removal instructions.
4. Unscrew the cap screws and washers (keys 34 and 63), and remove the cover (key 33).
5. Remove the retaining ring (key 30), and slide the hub (key 29) from the cover. If necessary, remove the travel indicator (key 37) from the hub (key 29).
6. Inspect, and if necessary, replace the cover bushing (key 31). Remove the travel indicator scale (key 35) by removing the self-tapping screws (key 36). Press the bushing out of the cover (key 33).
7. Remove the cap screw and hex nut (keys 18 and 19).
8. Make note of the lever/valve shaft orientation, and then loosen the cap screw (key 28).

CAUTION

When removing the actuator from the valve, do not use a hammer or similar tool to drive the lever (key 27) off the valve shaft. Driving the lever could damage internal valve parts. On some valve types, driving the lever off the shaft could move the valve disk or ball and bearings away from the centered position, causing subsequent damage to valve parts as the valve is operated.

A wheel puller may be used to remove the lever. It is okay to tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could also damage valve parts or disrupt the centered position of the valve disk and bearings.

9. Rotate the handwheel (if one is used) counterclockwise until the handwheel is not compressing the spring (key 11).

⚠ WARNING

To avoid personal injury from pre-compressed spring force suddenly thrusting the upper diaphragm casing (key 1) away from the actuator, relieve 1052 spring compression, or carefully remove 1051 casing cap screws before proceeding further.

10. To relieve spring compression:
 - Insert a round rod into one of the holes in the lower bearing seat (key 73). Use the rod to rotate the lower bearing seat, and move it away from the actuator casings. Continue rotating the lower bearing seat until spring compression is completely removed. Rod hole diameter is 19.1 mm (3/4 inch) for size 70 actuators.
 - Unscrew and remove the cap screws and hex nuts (keys 5 and 6), and then remove the upper diaphragm casing and the diaphragm (key 3).
11. Removing the diaphragm plate (key 4):
 - (1.) Remove the rod end bearing (key 17), the hex nut (key 16), turnbuckle (key 57), and the hex nut (key 58) from the diaphragm rod (key 10).
 - (2.) Pull the diaphragm plate (key 4) and attached parts out of the actuator. Then remove the cap screw (key 9) to separate the diaphragm plate and the diaphragm rod.
 - *For Size 70 actuators:* Remove the actuator spring (key 11) from the actuator. Remove the cap screws (key 21), then remove the spring barrel (key 12) from the actuator housing. If it is necessary to remove the spring adjustment parts, loosen the set screw (key 75), and unscrew the spring adjusting screw (key 74) from the spring barrel (key 12).

12. Unscrew the cap screws (key 23), and remove the actuator housing assembly (key 20).
13. Unbolt the mounting yoke (key 22) from the valve.
14. Check the bushing (key 67) in the mounting yoke. Press out and replace the bushing if necessary.

Assembly

This procedure assumes that the actuator was completely disassembled. If the actuator was not completely disassembled, start these instructions at the appropriate step. This procedure also assumes that the valve is removed from the pipeline for ease in actuator assembly and adjustment.

Key numbers are shown in figure 8.

1. **Installing the spring barrel (key 12):** If the spring barrel (key 12) was removed from the housing (key 20), align the spring barrel to the housing as described below to ensure that the offset hole in the base of the spring barrel will be located properly. The spring barrel need not be aligned in any particular position when placing it on the housing.
2. If the bushing (key 67) was removed, press in the new bushing. The end of the bushing should be flush with the bottom of the recess in the mounting yoke (key 22).
3. Slide the mounting yoke over the valve shaft, and secure it to the valve with the valve mounting cap screws.
4. Tighten the valve mounting cap screws to the bolting torque listed in step 6 of the Installation procedures.

⚠ WARNING

Exceeding any torque requirement may impair the safe operation of the actuator and lead to possible personal injury or property damage.

5. Refer to figure 4 for the desired orientation of the housing (key 20). Secure the housing to the mounting yoke with cap screws (key 23).
6. Coat with lithium grease (key 93) on the cap screw threads (key 9), and the tapered end of the diaphragm rod (key 10).
7. See figure 8.
- If the adjusting screw and attached parts were removed, first clean and then lubricate the upper threads of the adjusting screw (key 74) with lithium grease (key 76) as shown in figure 8. Install the lower bearing seat (key 73), the thrust bearing (key 71), the thrust bearing races (key 72), and the spring seat (key 13) onto the adjusting screw.
- First, clean and then coat the lower end of the adjusting screw with sealant (key 77) or equivalent thread-locking compound as shown in figure 8, and install the entire assembly into the spring barrel (key 12). Let the adjusting screw stand undisturbed for at least two hours after installation to allow the thread-locking compound to cure.

CAUTION

Apply lubricant to the upper threads and thread-locking compound to the lower threads of the adjusting screw. Do not overlap the coat of lubricant with the coat of thread-locking compound since this will adversely affect the performance quality of both substances.

8. Coat the tapered end of the diaphragm rod (key 10) and the threads of the cap screw (key 9) with lithium grease (key 76). Bolt the diaphragm plate to the diaphragm rod.
9. Be certain the travel stops (key 8) are located as shown in figure 5.

10. Install the spring (key 11) into the spring barrel. Install the diaphragm plate and diaphragm rod into the actuator. Attach the hex nut (key 58), turnbuckle (key 57), hex nut (key 16), and rod end bearing (key 17) to the diaphragm rod.

11. Installing the diaphragm:

- Install the diaphragm (key 3) and place the upper diaphragm casing (key 1) onto the lower diaphragm casing (key 2). If necessary, rotate the lower bearing seat (key 73) so that the upper diaphragm casing travel stop will not contact the diaphragm when the casing cap screws and nuts (key 5 and 6) are tightened.
- Secure the upper diaphragm casing with the cap screws and hex nuts (keys 5 and 6). Be sure the warning nameplate is in place on the casing. Tighten the nuts on the cap screws to the torque value shown in table 3.

Figure 5. Travel Stop Orientation

- Complete the Initial Setting portion of the 1052 Spring Adjustment section before proceeding.
- Refer to the appropriate valve instruction manual for lever/valve shaft orientation marks, and slide the lever (key 27) into place; see figure 4 for correct lever operating clearance. Clamp with the cap screw (key 28, figure 8).
- Rotate the lever (key 27) to align with the rod end bearing (key 17). This connection can be aided by carefully stroking the actuator off its up travel stop with a regulated air source.
- Apply sealant (key 77) or equivalent thread-locking compound to the threads of the cap screw (key 18).
- Connect the lever (key 27) and the rod end bearing (key 17) with the cap screw and hex nut (keys 18 and 19). Tighten the nut on the cap screw (see table 3).
- Coat the bearing surfaces of the hub (key 29), and cover (key 33) with lithium grease (key 76). Install the bushing (key 31) and hub into the cover. Secure with the retaining ring (key 30).
- Install the travel indicator scale (key 35), and secure it with the self-tapping screws (key 36). Then install the travel indicator (key 37), and secure it with the self-tapping screws (key 38).
- Note the valve disk or ball position, and direction of rotation. Position the travel indicator (key 37) accordingly.
- Replace the cover (key 33), and secure with cap screws and washers (keys 34 and 63). If the holes in the cover and housing (key 20) do not align, use a regulated air source to move the actuator slightly off the up travel stop. If hole alignment cannot be obtained in this manner, temporarily loosen cap screws (key 23), and shift the housing slightly.

CAUTION

To avoid parts damage, do not stroke the actuator while cover (key 33) is off.

21. If a valve positioner is to be used, consult the separate valve positioner instruction manual for proper positioner installation.
22. Follow the instructions in the Turnbuckle Adjustment section.

Changing Actuator Mounting

The actuator is normally positioned vertically in a horizontal pipeline. However, four mounting styles and four positions for each style are possible (see figure 3).

Note

Due to its weight, the 1052, size 70 actuator must be externally supported if mounted in the horizontal position.

Correct lever/valve shaft positioning is important to ensure proper valve action. Consult the appropriate valve instruction manual.

Style A is right-hand mounted, while style D is left-hand mounted. In all other ways, the styles A and D are identical.

Style B is right-hand mounted, while style C is left-hand mounted. In all other ways, the styles B and C are identical.

Use the following procedure along with figure 8, for key number references, to convert from styles A and D to styles B and C or vice versa or to change the mounting position.

WARNING

To avoid personal injury, perform the steps in the WARNING at the beginning of the Maintenance section to isolate the control valve and actuator.

1. Remove the tubing or piping from the top of the actuator.
2. Remove the cover (key 33) by unscrewing and removing the cap screws and washers (keys 34 and 63).
3. Unscrew cap screw (key 18). Loosen cap screw (key 28).

CAUTION

When removing the actuator from the valve body, do not use a hammer or similar tool to drive the lever (key 27) or actuator off the valve shaft. Driving the lever or actuator could damage internal valve parts. On some valve types, driving the lever (key 27) could move the valve disk and bearings away from the centered position causing subsequent damage to valve parts.

A wheel puller may be used to remove the lever. It is okay to tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could also damage valve parts or disrupt the centered position of the valve disk and bearings.

4. If changing styles,
 - Unscrew cap screws (key 23), and remove the actuator housing (key 20) from the mounting yoke (key 22).

- Rotate the housing 180 degrees, maintaining the appropriate position (1, 2, 3, or 4), and place the actuator onto the mounting yoke (key 22).
- 5. If changing positions, unscrew cap screws (key 23), and rotate the actuator housing to the desired position.
- 6. Secure actuator housing (key 20) to the mounting yoke (key 22) with cap screws (key 23). Consult table 3 for appropriate bolt torques.
- 7. Consult the appropriate valve instruction manual for lever/valve shaft orientation marks, and slide the lever (key 27) into place; see figure 4 for correct lever operating clearance. Clamp with the cap screw (key 28).
- 8. Rotate the lever (key 27) to align with the rod end bearing (key 17). This connection can be aided by stroking the actuator off its up travel stop with a regulated air source.
- 9. Apply sealant (key 77) or equivalent thread-locking compound to the threads of the cap screw (key 18).
- 10. Connect the lever (key 27) and the rod end bearing (key 17) with the cap screw and hex nut (keys 18 and 19). Tighten cap screw to the recommended bolt torque shown in table 3. This connection can be aided by stroking the actuator from its up travel stop with a regulated air source.
- 11. Note the valve position and direction of rotation. Position the travel indicator (key 37) accordingly. Replace the cover (key 33), and secure it with cap screws and washers (keys 34 and 63).
- If the holes in the cover and housing (key 20) do not align, use a regulated air source to move the actuator slightly off the up travel stop.
- If hole alignment cannot be obtained in this manner, temporarily loosen cap screws (key 23) and shift the housing slightly.

CAUTION

To avoid parts damage, do not stroke the actuator while cover (key 33) is off.

- 12. Follow the instructions given in the Turnbuckle Adjustment section.

Top-Mounted Handwheels and Adjustable Travel Stops

Principle of Operation for Handwheels

Note

If repeated or daily manual operation is expected or desired, the unit should be equipped with a manual handwheel actuator. Refer to the separate manual handwheel actuator instruction manual for mounting instructions.

Top-Mounted Handwheel Assembly is attached to a special upper diaphragm casing (key 1, figure 8) with cap screws (key 141, figure 9). A hex nut (key 137, figure 10) locks the handwheel in position. Turning the handwheel (key 51, figure 9) clockwise into the upper diaphragm casing forces the pusher (key 135, figure 9) against the diaphragm and diaphragm plate (keys 3 and 4, figure 8) to compress the spring (key 11, figure 8) and move the diaphragm rod downward.

Turning the handwheel counterclockwise allows the actuator spring to move the diaphragm rod upward.

- If the valve is push-down-to-close, full opening can be restricted by positioning the handwheel at the desired position.
- If the valve is push-down-to-open, full closing of the valve can be restricted by use of the handwheel.

Adjustable Up Travel Stop (figure 10) limits the actuator stroke in the upward direction. To make adjustments, first relieve actuator loading pressure before removing the closing cap (key 187) as it is a pressure retaining part. Remove the closing cap (key 187). Also, for size 70 actuators, the hex nut (key 137) must be loosened. Then turn the stem (key 133) clockwise into the diaphragm case to move the actuator stem downward or counterclockwise to allow the spring to move the actuator stem upward.

- If the valve has push-down-to-close action, full opening can be restricted by the position of the adjustable travel stop. Or,
- If the valve has push-down-to-open action, full closing can be restricted by the position of the adjustable travel stop.

Tighten the hex nut and replace the closing cap after adjustment.

Adjustable Down Travel Stop (figure 11) limits the actuator stroke in the downward direction. To make adjustments, first relieve actuator loading pressure before removing the closing cap (key 187) as it is a pressure retaining part. Remove the closing cap (key 187). Loosen the hex jam nut (key 189) and turn the hex nut (key 63) down on the stem (key 133) to limit travel, or up on the stem to allow more travel. Lock the jam nut against the hex nut, and replace the closing cap after the adjustment has been made.

Handwheel Maintenance and Adjustable Travel Stop

If loading pressure seems to be leaking from either the handwheel or adjustable up stop, the O-rings (key 138 and 139, figures 9 and 10) may need replacement. If the adjustable down stop leaks, the O-ring (key 139, figure 11) may need replacement or possibly the closing cap (key 187, figure 10) is not tight. To tighten the closing cap, apply a good grade of thread sealant to the closing cap threads.

For ease of operation, the stem threads (key 133, figures 9, 10, and 11) may need an occasional application of lithium grease (key 241). A grease fitting (key 169, figures 9 and 10) is provided for this purpose in the size 70. The size 70 may also need to have the thrust bearing (key 175, figures 9 and 10) packed with lithium grease (key 241). Travel stops for the smaller casings can be lubricated between the stem and pusher (key 135, figures 9 and 10) with lithium grease (key 241).

The following disassembly procedures are separated where appropriate between the top-mounted handwheel and adjustable up travel stop assemblies (figures 9 and 10) and the adjustable down travel stop assembly (figure 11).

WARNING

To avoid personal injury, perform the steps in the WARNING at the beginning of the Maintenance section to isolate the control valve and actuator.

1. Remove the tubing or pipe from the handwheel body (key 142, figures 9, 10, and 11).

WARNING

To avoid personal injury from the pre-compressed spring force thrusting the upper diaphragm casing (key 1, figure 8) away from the actuator, relieve 1052 spring compression by following the instructions that are referenced in the steps below before removing the casing.

2. Relieve all actuator spring compression by following the procedures presented in the Disassembly portion of the Maintenance section. Then, rotate either the handwheel (key 51, figure 9) or the travel stop stem (key 133, figures 10 and 11) counterclockwise until the handwheel or travel stop assembly is no longer compressing the spring.
3. Proceed as appropriate:

For Adjustable Up Travel Stops:

- a. Remove the upper diaphragm casing (key 1, figure 8) by following steps 1, 3, 7, 9, 10, and 11 of the Disassembly portion of the Maintenance section.
- b. Remove the cap screws (key 141, figures 9 and 10), and separate the assembly from the upper casing.
- c. Loosen the locknut (key 137, figure 9), or remove the closing cap (key 187, figure 10).
- d. Turn the stem (key 133, figures 9 and 10) clockwise out of the valve body. On handwheel assemblies, the cotter pin and hex nut (keys 247 and 54, figure 9) will have to be removed so that the handwheel (key 51, figure 9) and locknut can be taken off the stem first.
- e. Remove and inspect the O-rings (keys 138 and 139, figures 9 and 10); replace them if necessary.
- f. To complete disassembly:

The pusher unit is held to the stem by a retaining screw (key 174, figures 9, 10 or 11). Removing the retaining screw and pusher exposes the thrust bearing (key 175, figures 9 and 10) for inspection.

For Adjustable Down Travel Stops:

Key numbers are shown in figure 11 unless otherwise noted. For ease of operation, the stem (key 133) threads may need an occasional application of lubricant.

- a. Remove the closing cap (key 187), and unscrew the jam nut and hex nut (keys 189 and 63) off the stem (key 133).
 - b. Remove the upper diaphragm casing (key 1, figure 8) and travel stop body (key 142) by following steps 1, 3, 7, 9, 10, and 11 of the Disassembly portion of the Actuator Maintenance section.
 - c. Unscrew cap screws (key 141), and remove the body from the diaphragm case.
 - d. Check the condition of the O-ring (key 139), and replace it if necessary.
 - e. Loosen the hex nut (key 54), and then unscrew the travel stop stem (key 133) out of the actuator stem. The lower diaphragm plate (key 82) can now be removed and the rest of the actuator disassembled.
4. Reassemble by reversing the order of the disassembly steps, being sure to apply lubricant as previously mentioned and as shown by the lubrication boxes (key 241) in figures 9 and 10. For size 70 handwheels or up travel stop assemblies, coat the threads of the retaining screws (key 174, figures 9 and 10) with sealant (key 242) or equivalent thread-locking compound.

Figure 6. Actuator Locking Mechanism

5. Readjust the spring to obtain the appropriate travel stop restriction by following the steps in the Top Mounted Handwheel Assembly section, and then return the unit to operation.

Locking Mechanism

Refer to figure 6 when installing, operating, and locking the mechanism. Key numbers are shown in figure 6 unless otherwise noted.

Installing the Locking Mechanism

⚠ WARNING

To avoid personal injury, perform the steps in the **WARNING** at the beginning of the Maintenance section to isolate the control valve and actuator.

1. To add the locking mechanism to an existing actuator, contact your [Emerson sales office](#) or Local Business Partner to purchase the required parts. The required parts are the locking mechanism and a modified actuator housing.
2. To remove the old housing, use the Disassembly procedures in the Maintenance section.
3. Attach the mounting plate (key 123) to the modified housing (key 20) as shown in figure 6. Attach it with the cap screw (key 129). Make sure the hole in the center of the mounting plate lines up with the large tapped hole in the housing.
4. Make sure the jam nut (key 128) is threaded onto the threaded bolt before threading it into the housing.
5. After the bolt is threaded into the housing, install the groove pin (key 127) into the end of the bolt. (Note: The groove pin will prevent the threaded bolt from being totally unthreaded from the actuator housing.)

6. Make sure that the bolt is not threaded in so far that it will interfere with reassembly of the actuator.
7. Reassemble actuator using the Assembly procedure in the Maintenance section.
8. Make sure the actuator diaphragm rod is retracted fully. This will be the locked position of the valve. For a push-down-to-close valve and actuator, the valve will be fully open when locked. For a push-down-to-open valve and actuator, the valve will be fully closed when locked.
9. Screw the threaded bolt into the housing until it contacts the head on the lever cap screw (see figure 6).
10. Insert the padlock (customer supplied) to connect the mounting plate (key 123) with the lower locking disk on the mounting plate assembly (key 124). You might have to back off the lower locking disk a slight amount to line up the holes for the padlock.

CAUTION

The layers of the mounting plate assembly may be far enough apart that you will need to purchase a padlock with a longer loop. Do not attempt to force the layers closer to fit a small looped padlock, as property damage may result.

11. Tighten the jam nut (key 128) against the mounting plate.

Operating the Locking Mechanism

To Unlock the Actuator

1. Remove the padlock. Loosen the jam nut (key 128), and unscrew the threaded bolt until it is stopped by the groove pin (key 127) in the threaded bolt.

CAUTION

For normal operation of the actuator, the threaded bolt must be unscrewed far enough so that the actuator lever will not contact the bolt, which could lead to property damage.

2. If you are going to leave the bolt threaded into the housing, lock it by tightening the jam nut (key 128) against the mounting plate so that it cannot be screwed into the housing and interfere with normal actuator operation.

Figure 7. Pipe Away Vent Assembly

32A9325-F

NOTE:
IF ACCESSORIES ARE NOT INSTALLED ON THE MOUNTING BOSS, INSTALL CAP SCREWS (KEY 143) TO PLUG OPENINGS. A MOUNTING BOSS IS LOCATED ON BOTH SIDES OF THE SPRING BARREL.

ACCESSORIES MOUNTING BOSS

40B3945-B

NOTE:
INSTALL THE HEX HEAD PLUG (KEY 140) INTO THE VENT OPENING LOCATED IN THE ACTUATOR HOUSING.

HOUSING VENT PLUG LOCATION

34B4646-B

NOTE:
FOR FIELD CONVERSION OF 1052 ACTUATORS, ATTACH COVER (KEY 141) OVER THE SPRING BARREL ADJUSTMENT OPENING WITH SELF-TAPPING SCREWS (KEY 142). USE KEY 141 AS A DRILLING TEMPLATE. USE DRILL SIZE 2.6 mm (A #37 DRILL) (0.104-INCH) BY 9.6 mm (0.38-INCH) DEEP.
☐ APPLY SEALANT

mm
(INCH)

To Lock the Actuator

1. Make sure the actuator diaphragm rod is retracted fully. This will be the locked position of the valve. For a push-down-to-close valve and actuator, the valve will be fully open when locked. For a push-down-to-open valve and actuator, the valve will be fully closed when locked.
2. Make sure the jam nut (key 128) is loose. Screw the threaded bolt into the housing until it contacts the head on the lever cap screw (see figure 6).
3. Rotate the threaded bolt until one of the holes in the lower locking disk (which is welded to the bolt) is in line with the hole in the mounting plate (key 123). Tighten the jam nut against the mounting plate.
4. Lock the plate and disk together with a padlock. (The padlock is customer supplied.)

Pipe-Away Vent

⚠ WARNING

If a flammable or hazardous gas is being used as a supply medium, personal injury, or property damage could result from fire or explosion of accumulated gas. A remote vent pipe cannot be relied upon to vent all gases from the installed location. Provide adequate ventilation for the actuator/positioner assembly. Comply with local and regional codes, and keep the vent pipeline as short as possible with few bends.

Some applications require venting of gas from the rotary actuator housing. The 3610 Series positioners vent into the actuator housing, and from there, the gas has numerous avenues of escape.

Note

This modification is NOT intended to be a leak-proof or pressure-tight design. It is intended to aid in containing the gas that vents from the positioner and allow for connection of piping to carry it away.

Take care that an adequate vent pipe size is used. This is particularly important with the larger size actuators that have fast stroking speed requirements. In these situations, large quantities of gas can be vented very quickly through the positioner, and adequate pipe-away capability must be obtained. Keep the vent piping as short as possible with few bends.

Refer to the Disassembly and Assembly steps in the Maintenance section to gain access to the following parts. Key numbers are shown in figure 7 unless otherwise noted.

Bushings—Remove the mounting yoke bushing (key 67), and the end plate cover bushing (key 31, figure 8). Replace them with the pipe-away vent parts, as shown in figure 7. The mounting yoke bushing (key 132) is a two-piece bushing with an O-ring (key 133). The end plate cover completes the assembly with a two-piece bushing (key 134) with an O-ring (key 135).

Travel Indicator—A gasket (key 136) is placed under the travel indicator plate. Remove the indicator plate (key 37, figure 8), install the gasket (key 136) as shown in figure 7.

Access Plate Assembly—A modified metal access plate assembly (key 137) is provided with a 3/4 NPT vent connection as shown in figure 7. If the actuator had a plastic access plate, it will be necessary to drill and tap the actuator housing

to install the machine screws (key 138) as shown in figure 7. Use the drilling and tapping pattern shown in figure 7, or use the holes in the access plate as a template to mark holes.

When finished with all maintenance procedures requiring the access plate assembly (key 137) to be removed, use the sealant (key 139) provided with the kit to seal the plate in place.

Housing Vent Plug—A vent is provided in the housing design. To plug this opening, the pipe-away vent kit provides a hex pipe plug (key 140) for this opening, as shown in figure 7. Install the hex plug (key 140) into this opening and tighten it.

Accessories Mounting Boss—If accessories are not installed on the mounting boss, install cap screws (key 143) to plug openings. The location to install the cap screws (key 143) is shown in figure 7. A mounting boss is located on both sides of the spring barrel (key 12, figure 8).

1052 Spring Barrel Access Cover—For field conversion of 1052 actuators, attach the cover (key 141) over the spring barrel adjustment opening with self-tapping screws (key 142). Use key 141 as a drilling template. Drill size is 2.6 mm (A #37 drill) (0.104-inches) by 9.6 mm (0.38-inches) deep.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, refer to the serial number found on the actuator nameplate (key 41, figure 9).

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts Kits

Top-Mounted Handwheel Retrofit Kits

Kit provides parts to add a top-mounted handwheel. Kit Number 1 includes the handwheel assembly only. Kit Number 2 includes Kit Number 1 and a new upper case (key 1) that is required to mount the handwheel assembly.

Kit Number 1

Introduction

Scope of Manual

This instruction manual includes installation, adjustment, maintenance, and parts ordering information for the Fisher 1061 pneumatic piston rotary actuator with F and G mounting adaptations (see figure 1). Instructions for the control valve, the auxiliary declutchable handwheel actuator, the valve positioner, and accessories are covered in separate instruction manuals.

Do not install, operate, or maintain a 1061 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

--	--

1. The pressure/temperature limits in this manual and any applicable standard or code limitation for valves should not be exceeded.

Description

The 1061 actuator is a double-acting pneumatic piston rotary actuator for use with rotary-shaft valves having splined valve shafts. The 1061 actuator can be used for either throttling or on-off applications.

The style G mounting bracket is for Fisher 9500 valves only. The style F mounting bracket is for all other rotary valves.

Specifications

Specifications are shown in table 1 for 1061 actuators. Specifications are stamped on the nameplate. Refer to the actuator nameplate for the construction setting and serial number for the actuator when it originally came from the factory.

Educational Services

For information on available courses for 1061 Style F and G actuators, as well as a variety of other products, contact:

Emerson Automation Solutions
Educational Services - Registration
Phone: 1-641-754-3771 or 1-800-338-8158
E-mail: education@emerson.com
emerson.com/fishervalvetraining

Principle of Operation

Piston movement is accomplished by loading air pressure on one side of the piston, and unloading air pressure from the other side of the piston. If no positioner is used with the control valve, a loading device, such as a 4-way switching valve, must be provided. Such a device is not furnished with the actuator.

Refer to the separate valve positioner instruction manual for the 1061 actuator principle of operation with positioner.

Installation

When an actuator and valve are shipped together, the actuator is normally mounted on the valve. Follow the valve instructions when installing the control valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the procedures presented in the Actuator Mounting section.

WARNING

To avoid personal injury, always wear protective gloves, clothing, and eyewear when performing any installation operations.

To avoid personal injury or property damage caused by bursting of pressure retaining parts, be certain the service conditions do not exceed the limits given in table 1 or on the nameplate. Use pressure limiting or pressure relieving devices to prevent the cylinder pressure from exceeding the maximum allowable cylinder operating pressure.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

Actuator Mounting

Use the following steps to connect a valve and actuator that have been ordered separately, or if the valve or actuator were separated for maintenance purposes.

Key numbers used in this procedure are shown in figures 8, 9 and 11.

WARNING

Perform the steps in the WARNING at the beginning of the Maintenance section.

1. Refer to instructions in the appropriate valve instruction manual.
2. If a valve positioner is installed on the actuator, remove the positioner.

On the travel indicator side of the actuator:

3. Remove the cap screws and washers (keys 35 and 76), and remove the actuator cover (key 34). If an optional manual handwheel actuator is being used, it will be removed with the cover.
4. If the lever (key 28) is attached to the rod end bearing (key 12), remove the cap screw and hex nut:
 - For size 30, 40, 60, and 68 actuators, remove the cap screw and hex nut (keys 13 and 14).
 - For size 80 and 100 actuators, remove the cap screw, washer, and hex nut (keys 13, 84, and 85).
 - For size 130 actuators, remove the cap screw and locknut (keys 13 and 85).

On the valve side of the actuator:

5. The actuator is normally positioned vertically with the valve in a horizontal pipeline. Refer to figure 2 for available mounting styles and positions that match your application. Also, refer to the lever/shaft orientation provided in the valve instruction manual.

CAUTION

It is important, when installing the actuator on the valve, to be sure that the valve is positioned correctly.

- **Note the actuator style, position, and lever in relationship to the valve body and drive shaft end marks (see step 13, below).**
- **The valve internal components can be damaged if forced past its fully open or fully closed position.**

6. Screw the mounting yoke (key 23) onto the actuator, and tighten the screws (key 24). Slide the actuator onto the valve shaft, and secure the mounting yoke to the valve body with the valve mounting screws.
7. Tighten the valve mounting cap screws to the bolting torque values given in table 2.
8. Hold the valve in the correct position, and secure it with the cap screws (key 24).

A1579-5

Table 2. Bolting Torque Values for Valve Mounting Cap Screws

VALVE SHAFT DIAMETER		VALVE MOUNTING CAP SCREWS	
mm	Inch	N•m	lbf-ft
12.7 to 25.4	1/2 to 1	80	65
31.8 & 38.1	1-1/4 & 1-1/2	135	100
44.5 & 50.8	1-3/4 & 2	183	135
63.5	2-1/2	390	290
76.2 & 88.9	3 & 3-1/2	745	550

On the travel indicator side of the actuator:

9. Screw the left-hand threaded hex nut (key 71) onto the piston rod (key 10) as far as possible.
10. Screw the turnbuckle (key 70) onto the piston rod as far as possible. Only finger-tighten it, as this adjustment will be changed in a later step.
11. Screw the hex nut (key 11) onto the rod end bearing. Then thread this assembly completely into the turnbuckle.

Figure 3. Lever Operating Clearance

12. To aid installation of the lever, apply lithium grease lubricant (key 93) to the valve shaft spline.

For size 80, 100 and 130 actuators, it may be necessary to rotate the set screw (key 82) clockwise slightly to spread the split portion of the lever and allow installation on the valve shaft.

13. Refer to the appropriate valve instruction manual for lever/shaft orientation marks, and slide the lever into place. Refer to figure 3 for the appropriate lever operating clearance.

- For size 80, 100 and 130 actuators, when the lever is in place, back off the set screw (key 82) so the lever can be clamped onto the valve shaft.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

Instruction Manual

D100324X012

1061 F & G Actuator

June 2017

- For all sizes: Hold the lever in position, and secure the assembly with the cap screw (key 29).

14. Rotate the lever until the cap screw hole is aligned with the rod end bearing (key 12). You may need to adjust the turnbuckle to make this alignment.

15. For all actuator sizes, apply thread locking sealant (high strength) (key 83) to the cap screw (key 13) threads.

Table 3. Recommended Bolting Torques

WARNING

Refer to table 3 for bolt torque requirements. Exceeding any torque requirements could damage actuator parts and impair safe operation. Refer to the Warning at the beginning of the Installation section in this manual.

Note

If the cap screw key number is shown in table 3, torque the cap screws to the value shown in the table for final assembly.

16. Connect the lever to the rod end bearing with the cap screw and hex nut (keys 13 and 14) for size 30, 40, 60, and 68 actuators; with the cap screw, washer, and locknut (keys 13, 84, and 85) for size 80 and 100 actuators; or with the cap screw and hex nut (keys 13 and 85) for size 130. Torque cap screw and hex nut to the value listed in table 3.

17. Note the valve disk or ball position and direction of rotation.

⚠ WARNING

To avoid possible personal injury, do not stroke the actuator while the cover (key 34) is off.

a. If no handwheel actuator is to be used, position the travel indicator (key 38) according to the valve disk or ball position just noted. Replace the cover (key 34), and secure it with the washers and cap screws (keys 76 and 35). If the holes in the cover and housing (key 21) do not align, temporarily loosen the cap screws (key 24) and shift the housing slightly. Do not stroke the actuator while the cover is off.

b. If a manual handwheel actuator is to be used, refer to the separate instruction manual for mounting instructions.

18. If the 1061 actuator is equipped with an auxiliary handwheel actuator, make certain that a cylinder bypass valve (key 68, figure 10) is also used to equalize cylinder pressure during handwheel operation. Operating the handwheel actuator by itself against the force of differential cylinder pressures is difficult or even impossible. Install a bypass valve as shown in figure 10. If the actuator was equipped with a valve positioner, refer to the positioner instruction manual mounting procedures.

Changing Actuator Mounting

The actuator is normally positioned vertically in a horizontal pipeline. However, four mounting styles and four positions are possible for each style. See figure 2.

Be sure to refer to the appropriate valve instruction manual for lever/valve shaft orientation, when changing styles and/or positions. Most mounting changes will require the actuator lever to change position in relationship to the valve splined shaft. It is possible to damage the valve if the actuator drives the valve disk or ball past its fully open or fully closed position.

Refer to the Actuator Mounting section, to disassemble and assemble the actuator when changing the style or position of the actuator.

CAUTION

Do not use a hammer or similar tool to drive the lever (key 28) off the valve shaft. Driving the lever could damage internal valve parts. On some valves, driving the lever off the shaft could move the valve disk or ball and bearings away from the centered position, causing subsequent damage to valve parts as the valve is operated.

If necessary, use a wheel puller to remove the lever from the valve shaft. It is permissible to tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could damage valve parts or disrupt the centered position of the valve disk or ball and bearings.

When changing styles and/or positions, most mounting changes will require the actuator lever to change position in relationship to the valve splined shaft. It is possible to damage the valve if the actuator drives the valve disk or ball past its fully open or fully closed position.

Key numbers referenced in the following procedures are shown in figures 8, 9 and 11.

Changing Styles

Style A is right-hand mounted while Style D is left-hand mounted. In all other ways, styles A and D are identical.

Style B is right-hand mounted while Style C is left-hand mounted. In all other ways, styles B and C are identical.

The actuator housing, for style A & D is turned 180 degrees to convert it to a style B & C, or vice versa. In other words, the actuator cover (key 34) is removed and placed on the mounting yoke (key 23) side.

The mounting yoke is placed on the cover side of the actuator housing (key 21). The lever (key 28) must be removed and replaced during the procedure. Refer to figure 2 and note the relationship of the valve style and the pipeline.

Table 4. Open-End Wrench Size Required for Turnbuckle Adjustments, Inches

ACTUATOR SIZE	TURNBUCKLE (KEY 70)	LOWER LOCKNUT (KEY 11)	UPPER LOCKNUT (KEY 71)
30	1-1/8	3/4	1-1/8
40 & 60	1-5/16	1-1/8	1-5/16
68	1-7/8	1-1/8	(1)
80 & 100	1-7/8	1-7/8	1-7/8
130	2-3/4	2-3/4	2-3/4

1. A 3/8-inch diameter rod is used for tightening.

Changing Positions

The actuator housing (key 21) position, and its orientation with the mounting yoke (key 23) can be changed into four different positions. Refer to figure 2 and note the possible positions for each style.

Pressure Connections

1. Connect either pipe or tubing between the actuator pressure connections and the instrument. Keep the length of pipe or tubing as short as possible to avoid transmission lag in the control signal.
2. When the control valve is completely installed and connected to the instrument, check for correct action (air-to-open or air-to-close) to match the controlling instrument. For successful operation, the actuator stem and valve shaft must move freely in response to the loading pressure change on the piston.

Adjustment

The only adjustment on the 1061 actuator is to make sure that the valve disk or ball is correctly closed when the actuator piston is against the travel stop. For accurate adjustment to the zero-degree valve disk or ball position, you must remove the control valve from the pipeline. Refer to the valve instruction manual for instructions during this procedure.

If the actuator is equipped with a manual handwheel actuator, make sure that the manual actuator is disengaged from the valve shaft and that the bypass valve (key 68, figure 10) is closed before you perform adjustment procedures.

Perform the following steps to adjust the actuator turnbuckle. A regulated air supply will be required to stroke the actuator during this procedure. Also, when you perform this adjustment, refer to table 4 for the sizes of open-end wrenches required to loosen and tighten the hex nuts and turnbuckle.

Key numbers referenced in this procedure are shown in figures 8, 9, and 11.

WARNING

Perform the steps in the WARNING at the beginning of the Maintenance section.

1. Refer to instructions in the appropriate valve instruction manual.

2. Remove the access plate (key 72). Also remove the machine screws (key 73) if present.

Note

The cover (key 34) supports the outer end of the valve shaft and should not be removed during actuator adjustment.

3. Stroke the actuator until you can reach the lower hex nut (key 11) through the access opening. Loosen the hex nut.
4. Stroke the actuator until you can reach the left-hand threaded upper hex nut (key 71) through the access opening. Loosen the hex nut.
5. Perform one of the following:
 - a. **Push-down-to-close** (extending piston rod closes the valve): Slowly stroke the actuator to the down travel stop. Refer to the appropriate valve instruction manual to determine the closed position of the valve. Adjust the turnbuckle (key 70) until the valve is in the closed position. Lock this adjustment with the left-hand threaded hex nut (key 71). Stroke the actuator to the up travel stop, and tighten the lower hex nut (key 11). Check thread engagement distance. The thread engagement should be the distance of the diameter of the thread. Tighten the lower hex nut (key 11) using the torque values shown in table 3.
 - b. **Push-down-to-open** (extending piston rod opens the valve): Stroke the actuator to the up travel stop. Refer to the appropriate valve instruction manual to determine the closed position of the valve. Check the valve position. Stroke the actuator until you reach the turnbuckle (key 70) through the access opening. Adjust the linkage. Stroke the actuator to the up travel stop again, and check the new adjustment. Continue this procedure until the valve is in the closed position when the actuator piston is resting against the up travel stop. Check thread engagement distance. The thread engagement should be the distance of the diameter of the thread. Tighten the lower hex nut (key 11) using the torque values shown in table 3.
6. Replace the access plate (key 72).
7. Loosen the self-tapping screws (key 39), and adjust the travel indicator (key 38). Re-tighten the self-tapping screws.

CAUTION

If using a handwheel actuator, the valve shaft spline could be damaged if excessive torque is applied to the valve shaft by the manual actuator while the 1061 power actuator is stopped at either end of travel. To protect the valve shaft, perform the travel stop adjustment procedure found in the separate handwheel actuator instruction manual.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions. Instructions are given below for disassembly and replacement of parts.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.

- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Key numbers are shown in figures 8, 9 and 11.

Disassembly

The following procedure describes how to completely disassemble the actuator. When inspecting and replacing parts, perform only those steps necessary to accomplish the repair.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment. Refer to instructions in the appropriate valve instruction manual.
2. Remove the positioner, if one is used. If necessary, refer to the positioner instruction manual for removal instructions.
3. Unscrew the cap screws and washers (keys 35 and 76), and remove the cover (key 34). If an optional manual handwheel actuator is used, it will be removed with the cover. Refer to the separate handwheel actuator instruction manual for instructions.
4. Remove the retaining ring (key 31). If necessary, remove the travel indicator (key 38), by removing the screws (key 29) from the hub (key 30).
5. Inspect, and if necessary, replace the cover bushing (key 32). Remove the travel indicator scale (key 36) by removing the self-tapping screws (key 37). Press the bushing out of the cover (key 34).
6. Remove the cap screw and hex nut (keys 13 and 14) for size 30, 40, 60, and 68 actuators; the hex nut and washer (keys 85 and 84) for size 80 and 100 actuators; or the cap screw and heavy hex nut for size 130 (key 13 and 85).
7. Note the lever/valve shaft orientation. Loosen cap screw (key 29). For size 80, 100 and 130 actuators, rotate set screw (key 82) clockwise slightly to spread the split portion of the lever (key 28).

CAUTION

When removing the actuator from the valve, do not use a hammer or similar tool to drive the lever (key 28) off the valve shaft. Driving the lever could damage internal valve parts. On some valves, driving the lever off the shaft could move the valve disk or ball and bearings away from the centered position, causing subsequent damage to valve parts as the valve is operated.

If necessary, use a wheel puller to remove the lever from the valve shaft. It is permissible to tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could damage valve parts or disrupt the centered position of the valve disk or ball and bearings.

8. For size 30, 40, and 68 actuators, unscrew cap screws (key 6) and remove cylinder cap (key 4). Inspect and, if necessary, replace the O-ring (key 5).
9. Remove rod end bearing (key 12) and hex nut (key 11), remove the turnbuckle (key 70) and hex nut (key 71).
10. Remove cap screws (key 3) and slide the cylinder assembly (key 1) from the cylinder flange (key 2).
11. Pull the piston (key 7) and piston rod (key 10) from the cylinder assembly.
12. Inspect and, if necessary, replace the O-rings (keys 8 and 16).
13. To separate the piston (key 7) from the piston rod (key 10), unscrew the cap screw or hex nut and washer (keys 9 and 77) for size 30, 40, 60 and 68 actuators or the hex nut (key 86) for size 80 and 100 actuators.
14. For the size 130 actuator, a piston rod disassembly fixture (figure 4) is recommended to properly disassemble the piston from the piston rod. Consult your [Emerson sales office](#) or Local Business Partner if this assembly must be disassembled.
15. Unscrew the cap screws (key 22) and remove the cylinder flange (key 2), sliding seal (key 19), and seal support cylinder (key 20).
16. Inspect, and if necessary, replace the O-rings (keys 17 and 18) and thrust washer (key 74).
17. Unscrew the cap screws (key 24) from the mounting yoke, and remove the actuator housing assembly (key 21).
18. Unscrew the mounting yoke (key 23) from the valve by removing the valve mounting cap screws. Slide the yoke off the valve shaft.
19. Inspect, and if necessary replace the mounting yoke bushing (key 81). It may be necessary to press out the bushing.

Assembly

This procedure assumes that the actuator was completely disassembled. If the actuator was not completely disassembled, start these instructions at the appropriate step. This procedure also assumes that the valve is removed from the pipeline for ease in actuator assembly and adjustment.

Key numbers used in the following procedures are shown in figures 8, 9, and 11.

Note

Many of the replacement mounting yokes (key 23) are available only as assemblies that also include the bushing (key 81). However, replacement bushings are also available separately (see the Parts List).

1. If the bushing (key 81) was removed, press in the new bushing. The end of the bushing should be flush with the bottom of the recess in the mounting yoke (key 23).
2. Slide the mounting yoke over the valve shaft, and secure it to the valve with the valve mounting cap screws.
3. Tighten the valve mounting cap screws to the bolting torque values given in table 2.

WARNING

Refer to table 3 for bolt torque requirements. Exceeding any torque requirements could damage actuator parts and prevent safe operation. Refer to the Warning at the beginning of the Installation section in this manual.

Note

The cap screws torque values shown in table 3 are for final assembly.

4. Refer to figure 2 for the desired orientation of the housing (key 21). Secure the housing to the mounting yoke with the cap screws (key 24).
5. Apply lithium grease lubricant (key 93) to the surfaces of the sliding seal (key 19). Refer to torque values shown in table 3. Be sure the O-rings (keys 17 and 18) are inserted correctly.

Note

When assembling parts, make sure that all O-rings are positioned correctly as shown in figures 8, 9, and 11.

6. Install the seal support cylinder (key 20), the thrust washer (key 74), the sliding seal, and the cylinder flange (key 2) and secure these parts with the cap screws (key 22).
7. If 60-degree rotation is specified, a travel stop (key 15) will be threaded into the cylinder flange on size 30 to 100. For size 130, a travel stop and travel stop sleeve (keys 15 and 6) will be put into the cylinder flange.
8. Apply lithium grease lubricant (key 93) to the valve shaft. Refer to the appropriate valve instruction manual for lever/valve shaft orientation marks, and slide the lever (key 28) into place. See figure 3 for correct lever operating clearance.

Figure 4. Piston Rod Assembly Fixture for Size 130 Actuator

58B3070
E0577

For Size 80, 100 and 130 actuators, rotate the set screw (key 82) clockwise slightly to spread the split portion of the lever and allow easy installation onto the shaft. After the lever is properly positioned, back-off the set screw so that the lever can be clamped to the shaft.

9. Hold the lever in place (see figure 3), and clamp the lever to the valve shaft with the cap screw (key 29).
10. Apply lithium grease lubricant (key 93) to the sealing surface of the piston rod (key 10) and apply anti-seize sealant (key 91) to the tapered end of the piston rod on all sizes except 130.
11. Attach the piston (key 7) to the piston rod, applying thread locking adhesive (medium strength) (key 92) to the threads (key 9 or 10):
 - a. For Size 30, 40, and 60 actuators: Secure it with the cap screw and washer (keys 9 and 77).
 - b. For Size 68 actuators: Secure it with the hex nut and washer (keys 9 and 77).
 - c. For Size 80 and 100 actuators: Secure it with the hex nut (key 86).
 - d. For the Size 130 actuator a piston rod assembly fixture (figure 4) is recommended to properly assemble the piston to the piston rod because of the high torque required and the need to properly protect the sealing surface of the

piston rod. Consult your [Emerson sales office](#) or Local Business Partner for additional information to properly assemble these parts.

- e. Tighten the screw or nut to the torque specified in table 3.
 12. Insert the piston and piston rod assembly down through the sliding seal (key 19). Attach the hex nut (key 71), turnbuckle (key 70), hex nut (key 11), and rod end bearing (key 12) to the piston rod assembly.
 13. Rotate the lever to align with the rod end bearing. This connection can be aided by carefully moving the piston/rod assembly up or down.
 14. Apply thread locking adhesive (medium strength) (key 92) or equivalent thread-locking compound to the threads of the cap screw (key 13).
 15. **Connecting the lever to the rod:**
 - *For Size 30, 40, 60, and 68 actuators:* Connect the lever and the rod end bearing with the cap screw and hex nut (keys 13 and 14).
 - *For Size 80, 100, and 130 actuators:* Connect the lever and the rod end bearing with the cap screw, washer, and hex nut (keys 13, 84, and 85). Size 130 does not require the washer (key 84).
 16. Install the O-ring (key 8 or 16) on the piston edge. Apply lithium grease lubricant (key 93) to the inside wall of the cylinder. Install the cylinder (key 1).
 17. Attach the cylinder assembly (key 1) to the cylinder flange with the cap screws (key 3).
- Size 130 has a mark on the cylinder flange that must align with a mark near the top of the housing flange.
18. *For Size 30, 40, and 68 actuators,* Place the O-ring (key 5) in the cylinder cap, replace the cylinder cap (key 4), and secure it to the cylinder assembly with the cap screws (key 6). Tighten all cap screws to the torques specified in table 3.
 19. Install the hub (key 30) plus bushing (key 32) into the cover (key 34), and secure with the retaining ring (key 31).
 20. Replace the travel indicator scale (key 36), and secure it with the self-tapping screws (key 37). Install the travel indicator (key 38), and secure it with the self-tapping screws (key 39).
 21. Note the valve disk or ball position and direction of rotation.

WARNING

To avoid possible personal injury, do not stroke the actuator while the cover (key 34) is off.

- a. If no handwheel actuator is to be used, position the travel indicator (key 38) according to the valve disk or ball position just noted. Replace the cover (key 34) and secure it with the cap screws and washers (key 35 and 76). If the holes in the cover and housing do not align, temporarily loosen the cap screws (key 24) and shift the housing slightly. Do not stroke the actuator while the cover is off.
 - b. If the actuator is equipped with a manual handwheel actuator, refer to the separate instruction manual for mounting procedures.
22. If a positioner is to be used, refer to the separate valve positioner instruction manual for proper installation.
 23. Follow the instructions in the Adjustment section for correct actuator turnbuckle adjustment.

Locking Mechanism

To add the locking mechanism to an existing actuator, purchase the retrofit kit to install this modification or order individual parts from your [Emerson sales office](#) or Local Business Partner. Replacement parts are shown in the Parts List section.

Figure 5. Locking Mechanism (Size 30, 40, 60, and 68)

Installing the Locking Mechanism

Refer to figures 5 and 6 for locking mechanism details and key number locations.

⚠ WARNING

Perform the steps in the **WARNING** at the beginning of the Maintenance section.

1. Refer to instructions in the appropriate valve instruction manual.
2. Disassemble the actuator by following the procedures in the Disassembly section.

For Size 30, 40, 60, & 68 Actuators

1. Attach the mounting plate (key 123) to the modified housing (key 21) as shown in figure 5. Attach it with the cap screw (key 129). Be sure the hole in the center of the mounting plate lines up with the large tapped hole in the housing.
2. Be sure the jam nut (key 128) is threaded onto the threaded bolt on the mounting plate assembly (key 124) before threading it into the housing.
3. After the bolt is threaded into the housing, install the groove pin (key 127) into the end of the bolt. (The groove pin will prevent the threaded bolt from being totally unthreaded from the actuator housing.)

Figure 6. Locking Mechanism (Size 80 and 100)

4. Make sure that the bolt is not threaded in so far that it will interfere with re-assembly of the actuator.
5. Be sure the actuator piston rod is retracted fully. This will be the locked position of the valve. For a push-down-to-close valve and actuator, the valve will be fully open when locked. For a push-down-to-open valve and actuator, the valve will be fully closed when locked.
6. Screw the threaded bolt into the housing until it contacts the actuator lever cap screw.
7. Insert the padlock (not furnished) to connect the mounting plate (key 123) with the lower locking disk on the mounting plate assembly (key 124). You might have to back off the lower locking disk a slight amount to line up the holes for the padlock.
8. Tighten the jam nut (key 128) against the mounting plate.
9. Refer to the Operating the Locking Mechanism section.

For Size 80 & 100 Actuators

1. Attach the mounting plate (key 123) to the modified housing (key 21) as shown in figure 6. Attach it with the four cap screws (key 129).
2. Thread the lock screw (key 131) into the mounting bracket.
3. Make sure that the lock screw is not threaded in so far that it will interfere with re-assembly of the actuator.
4. Be sure the actuator piston rod is retracted fully. This will be the locked position of the valve. For a push-down-to-close valve and actuator, the valve will be fully open when locked. For a push-down-to-open valve and actuator, the valve will be fully closed when locked.
5. Screw the lock screw into the housing until it contacts the actuator lever (key 28).
6. Screw the safety lockout (key 130) onto the mounting plate (key 123) until finger-tight. Then back it off until the hole in the arm of the safety lockout aligns with the hole in the mounting plate for the padlock.
7. Insert the padlock (not furnished) to connect the mounting plate (key 123) with the arm of the safety lockout (key 130). If the shackle of the padlock does not seem long enough, do not attempt to modify the actuator. The larger 1061 sizes may require a padlock with a longer shackle.
8. Refer to the Operating the Locking Mechanism section.

Operating the Locking Mechanism

Key numbers are located in figures 5 and 6.

To Unlock the Actuator (Size 30, 40, 60, & 68)

1. Remove the padlock. Loosen the jam nut (key 128, figure 5), and unscrew the threaded bolt until it is stopped by the groove pin (key 127) in the threaded bolt.

Note

For normal operation of the actuator, the threaded bolt must be unscrewed far enough so that the actuator lever will not contact the bolt in normal actuator operation.

2. If you are going to leave the bolt threaded into the housing, lock it with the jam nut (key 128) so that it cannot be screwed into the housing and interfere with normal actuator operation.

To Unlock the Actuator (Size 80 & 100)

1. Remove the padlock. Remove the safety lockout (key 130, figure 6) and unscrew the lockscrew until it is free of the lever path.

Note

For normal operation of the actuator, the threaded bolt must be unscrewed far enough so that the actuator lever will not contact the bolt in normal actuator operation. A good rule of thumb is to unscrew the lockscrew until it is approximately even with the outward edge of the safety lockout when installed.

2. If you are going to leave the bolt threaded into the housing, reinstall the safety lockout and padlock.

To Lock the Actuator (Size 30, 40, 60, & 68)

1. Be sure the actuator piston rod is retracted fully. This will be the locked position of the valve. For a push-down-to-close valve and actuator, the valve will be fully open when locked. For a push-down-to-open valve and actuator, the valve will be fully closed when locked.
2. Be sure the jam nut (key 128, figure 5) is loose. Then, screw the threaded bolt into the housing until it contacts the head on the cap screw of the actuator lever.
3. Rotate the threaded bolt until one of the holes in the lower locking disk (which is welded to the bolt) is in line with the hole in the mounting plate (key 123). Tighten the jam nut against the mounting plate.
4. Lock the plate and disk together with a padlock (not furnished).

To Lock the Actuator (Size 80 & 100)

1. Be sure the actuator piston rod is retracted fully. This will be the locked position of the valve. For a push-down-to-close valve and actuator, the valve will be fully open when locked. For a push-down-to-open valve and actuator, the valve will be fully closed when locked.
2. Screw the lockscrew (key 131) into the housing until it contacts the actuator lever (key 28, figure 9).
3. Screw the safety lockout (key 130) onto the mounting plate (key 123) until finger-tight. Then back it off until the hole in the arm of the safety lockout aligns with the hole in the mounting plate for the padlock.
4. Insert and lock the padlock (not furnished) to connect the mounting plate (key 123) with the arm of the safety lockout (key 130). The larger 1061 sizes may require a padlock with a longer shackle.

Pipe-Away Vent

Some applications require venting of gas from the rotary actuator housing. The 3610 Series positioners vent into the actuator housing, and from there, the gas has numerous avenues of escape.

⚠ WARNING

If a flammable, hazardous, or reactive gas is used as the supply pressure medium, personal injury or property damage could result from fire or explosion of accumulated gas or from contact with hazardous or reactive gas.

The positioner on the control valve assembly does not form a gas-tight seal. If the assembly is in an enclosed area, use a remote vent line, and use other safety measures to adequately ventilate the assembly. A remote vent pipe alone cannot be relied upon to remove all hazardous gas.

Vent line piping should comply with local and regional codes. It should be as short as possible with adequate inside diameter and few bends to remove exhaust gases to a ventilated area.

Note

This modification is NOT intended to be a leak-proof or pressure-tight design. It is intended to aid in containing the gas that vents from the positioner and allow for connection of piping to carry it away.

The Parts List section, at the end of this manual, provides...

- Retrofit kit numbers to modify an actuator for the vent piping
- Replacement parts for pipe-away vents
- Retrofit kit numbers for modification of units in the field

Take care that adequate vent pipe size is used. This is particularly important with the larger size actuators with fast stroking speed requirements. In these situations, large quantities of gas can be vented very quickly through the positioner, and you must have adequate pipe-away capability. Keep the vent piping as short as possible with few bends.

Key numbers are shown in figure 7 unless otherwise noted. Refer to the actuator Disassembly and Assembly steps to gain access to the following parts.

For installation and maintenance of the pipe-away vent system, be sure to do the following:

⚠ WARNING

Perform the steps in the WARNING at the beginning of the Maintenance section.

Refer to instructions in the appropriate valve instruction manual.

Bushings—Remove the mounting yoke bushing (key 67), and the end plate cover bushing (key 31, figures 9 and 11), then replace them with the pipe-away vent parts. As shown in figure 7, the mounting yoke bushing (key 132) has two pieces with an O-ring (key 133) between them. The end plate cover repeats the assembly with a two-piece bushing (key 134) with an O-ring between them (key 135).

Travel Indicator—A gasket (key 136) is placed under the travel indicator plate. Remove the indicator plate (key 37, figures 8, 9 and 11), install the gasket (key 136) as shown in figure 7.

Housing Vent Plug—A vent is provided in the housing design. To plug this opening, the pipe-away vent kit provides a hex pipe plug (key 140) for this opening as shown in figure 7. Install the hex plug (key 140) into this opening and tighten it.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, refer to the serial number found on the actuator nameplate.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

and Fisher 3610JP Positioner

Introduction

Scope of Manual

This instruction manual includes installation, adjustment, maintenance, and parts ordering information for the Fisher 1061 pneumatic piston rotary actuator (sizes 30, 40, 60, and 68) with H and J mounting adaptations (see figure 1). Instructions for the positioner, accessories, and, if used, the auxiliary handwheel actuator are covered in separate instruction manuals.

Do not install, operate, or maintain a 1061 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

Table 1. Specifications

Available Configuration Double-acting pneumatic piston rotary actuator for ■ throttling service when used with positioner or ■ on-off service when used with switching devices. Mounting adaptations include ■ H mounting for rotary actuation of equipment other than Fisher valves or ■ J mounting for rotary actuation of Fisher keyed-shaft butterfly valves and other keyed-shaft equipment Actuator Sizes ■ 30, ■ 40, ■ 60, and ■ 68 Cylinder Operating Pressure Minimum Recommended: ■ 1.4 bar (20 psig) without positioner or ■ 0.3 bar (5 psig) above actuator requirement with positioner⁽¹⁾ Maximum Allowable: Sizes 30 and 40: 10.3 bar (150 psig) Size 60: 6.9 bar (100 psig) Size 68: 5.9 bar (85 psig) Torque Limits Limited by maximum cylinder operating pressure or by tables 2 and 3, whichever is less	Maximum Valve Shaft Rotation ■ 90 degrees or ■ 60 degrees (travel stop required for 60 degrees rotation) Stroking Time Dependent on actuator size, degrees of rotation, and positioner if used. If stroking time is critical, contact your Emerson sales office or Local Business Partner. Material Temperature Capabilities With Standard Elastomers -34 to 82°C (-30 to 180°F) Pressure Connections ■ 1/4 NPT internal (Standard) ■ 1/2 and 3/4 optional on size 68 Travel Indication Graduated scale and pointer located on actuator cover at actuator end of valve shaft Mounting Positions See figure 4 Approximate Weights See table 4
--	--

1. See separate manual for positioner specifications.

Description

The 1061 actuator is a pneumatic piston rotary actuator for use with rotary control valves and other equipment. The H mounting adaptation permits the actuator to be used with user-provided mounting brackets and couplings for rotary actuation of equipment other than Fisher valves. The J mounting adaptation permits the actuator to be used for rotary actuation of Fisher keyed-shaft butterfly valves and other keyed-shaft equipment that can mount on the actuator yoke.

The H mounting adaptation includes a flat-surface mounting plate that is drilled and tapped for attaching the user-provided bracket. Cap screws for attaching the bracket are provided. H mounting also includes an output shaft (with milled flats) to provide the rotary output either directly or through a user-provided coupling⁽¹⁾. Output shaft diameters and torque limits are listed in table 2. Dimensional information for the mounting plate and output shaft are shown in figure 2.

The J mounting adaptation uses the standard butterfly valve mounting bracket and provides an output shaft with an attached coupling for keyed equipment shafts. Coupling sizes and torque limits are listed in table 3. Dimensional information for the mounting yoke and output shaft coupling is shown in figure 2.

Additionally, the 1061 actuator can be used for either throttling or on-off applications. For auxiliary manual operation of the equipment, a side-mounted handwheel actuator is available.

Specifications

Specifications are shown in table 1 for 1061 actuators. Specifications for a given 1061 actuator as it originally comes from the factory are stamped on a nameplate (key 42, figure 6) attached to the actuator.

Educational Services

For information on available courses for 1061 Style H and J actuators, as well as a variety of other products, contact:

Emerson Automation Solutions
Educational Services - Registration

E-mail: education@emerson.com
emerson.com/fishervalvetraining

Installation

When an actuator and valve are shipped together, the actuator is normally mounted on the valve. Follow the valve instructions when installing the control valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the procedures presented in the Actuator Mounting section.

⚠ WARNING

To avoid personal injury, always wear protective gloves, clothing, and eyewear when performing any installation operations.

To avoid personal injury or property damage caused by bursting of pressure retaining parts, be certain the service conditions do not exceed the limits given in table 1 or on the nameplate. Use pressure limiting or pressure relieving devices to prevent the cylinder pressure from exceeding the maximum allowable cylinder operating pressure.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

Table 2. Output Shaft Diameters and Torque Limits for Actuators With H Mounting

ACTUATOR SIZE	OUTPUT SHAFT DIAMETER		TORQUE LIMIT FOR H MOUNTING	
	mm	Inches	N•m	Lbf•in
30	22.2	7/8	240	2120
	28.6	1-1/8	468	4140
	38.1	1-1/2	1110	9815
40, 60 & 68	28.6	1-1/8	468	4140
	38.1	1-1/2	1210	10,680
	50.8	2 ⁽¹⁾	2650	23,430

1. Coupling supplied for mating with either 44.5 or 50.8 mm (1-3/4 or 2-inch) keyed shaft.

Table 3. Acceptable Shaft Diameters and Torque Limits for Actuators with J Mounting

ACTUATOR SIZE	COUPLING AVAILABILITY BY KEYED SHAFT DIAMETER		TORQUE LIMIT FOR J MOUNTING	
	mm	Inches	N•m	Lbf•in
30	9.5	3/8	52	460
	12.7	1/2	69	610
	15.9	5/8	114	1010
	19.1	3/4	207	1830

40, 60, & 68	19.1	3/4	207	1830
	25.4	1	468	4140
	31.8	1-1/4	1030	9110
	38.1	1-1/2	1360	12,000

Table 4. Approximate Actuator Weights

ACTUATOR SIZE	ALUMINUM HOUSING CONSTRUCTION		CAST IRON HOUSING CONSTRUCTION	
	kg	Pounds	kg	Pounds
30	18	39	22	49
40	23	50	29	63
60	33	73	39	86
68	50	110	56	123

Actuator Mounting

Use the following steps to connect the actuator to a valve or other equipment. Unless otherwise specified, key numbers are shown in figure 6.

WARNING

Perform the steps in the WARNING at the beginning of the Maintenance section.

Note

For an actuator with an H mounting adaptation and a 22.2 through 38.1 mm (7/8 through 1-1/2 inch) output shaft, find dimensions and center of gravity information in figures 2 and 3, and approximate weights in table 4. This information is required for proper fabrication of the user-provided bracket and coupling.

1. For an actuator with an H mounting adaptation, attach an appropriate mounting bracket (not provided) to the mounting plate (key 23) with the cap screws (key 87). See figure 2 for mounting dimensions on the mounting plate.
2. Consult figure 4 for available mounting styles and positions. The actuator is normally positioned vertically with the valve or other equipment in a horizontal pipeline.

Note

If the milled flats or the coupling on the end of the actuator output shaft (key 94) are oriented such that the output shaft cannot accommodate the operated equipment shaft, refer to the Changing Positions portion of the Changing Actuator Mounting section. This procedure describes how the output shaft can be repositioned to accommodate the operated equipment shaft.

3. If using an actuator with a J mounting adaptation, note that the valve shaft coupling (key 97) is furnished with two keyways lettered A & B as shown in figure 5 (letters C and D on the coupling are not used and can be disregarded).

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

Instruction Manual

D100325X012

1061 H & J Actuator

June 2017

Align the appropriate keyway with the keyway in the operated equipment shaft. If using a Fisher butterfly valve, align the appropriate keyway on the coupling with the valve shaft keyway indicated in table 5. Then, install the woodruff key (key 98) in the shaft keyseat, and slide the coupling onto the shaft. It is helpful to apply a light coat of grease to the inside of the coupling before sliding it onto the shaft.

4. For an actuator with a J mounting adaptation, secure the mounting yoke (key 23) to the valve with the cap screws (key 87, not shown). For 31.8 and 38.1 mm (1-1/4 and 1-1/2 inch) valve shafts, place two spacers (key 99, not shown) between the mounting yoke and valve or other equipment during this step.
5. For an actuator with an H mounting adaptation and a 22.2 through 38.1 mm (7/8 through 1-1/2 inch) output shaft, slide the actuator (with the user-provided mounting bracket attached) into the user-provided coupling on the operated shaft. Then, secure the actuator to the operated equipment in the desired mounting position with appropriate fasteners, such as mounting cap screws. See figure 2 for output shaft dimensions.
6. For an actuator with an H mounting adaptation and a 50.8 mm (2-inch) output shaft (key 94, figure 7), note that the valve shaft coupling (key 97, figure 7) is furnished with two keyways lettered A and B as shown in figure 5 (letters C and D on the coupling are not used and can be disregarded). Align the appropriate keyway with the keyway in the operated equipment shaft. Then, install the woodruff key (key 98, not shown in figure 7) in the shaft keyseat, and slide the coupling onto the shaft using the appropriate coupling keyway (see table 5 and figure 5). It is helpful to apply a light coat of grease to the inside of the coupling before sliding it onto the shaft. Secure the actuator (user-provided mounting bracket) to the operated equipment in the desired mounting position with appropriate fasteners, such as mounting cap screws.
7. If the 1061 actuator is equipped with an auxiliary handwheel actuator, make certain that a cylinder bypass valve (key 68, figure 8) is used to equalize cylinder pressure during handwheel operation. Operating the handwheel actuator by itself against the force of differential cylinder pressures is difficult or even impossible. An installation of a bypass valve is shown in figure 8.

CAUTION

Attempting to pneumatically operate the 1061 actuator while an auxiliary manual actuator is engaged could damage the actuator shaft. Be certain the manual actuator is disengaged before pneumatically operating the 1061 actuator.

8. Follow the instructions given in the Adjustment section before proceeding to the loading connection portion of this section.

Table 5. Keyway Alignment Information⁽¹⁾

DESIRED ACTUATOR ACTION	DESIRED SHAFT ROTATION, DEGREES	ACTUATOR MOUNTING POSITION	COUPLING KEYWAY TO USE ⁽³⁾	VALVE SHAFT KEYWAY TO USE FOR FISHTAIL™ DISK VALVES ⁽²⁾ (SEE FIGURE 6)			
				Clockwise to Close Valve Action ⁽⁴⁾		Counterclockwise to Close Valve Action ⁽⁴⁾	
				Flow Left to Right ⁽⁴⁾	Flow Right to Left ⁽⁴⁾	Flow Left to Right ⁽⁴⁾	Flow Right to Left ⁽⁴⁾
Push Down to Open (PDTO)	60 or 90	1	B	Nose	Tail	Tail	Nose
		2	A	Tail	Nose	Nose	Tail
		3	B	Tail	Nose	Nose	Tail
		4	A	Nose	Tail	Tail	Nose
Push Down to Close (PDTC)	60 ⁽⁵⁾ or 90	1	A	Tail	Nose	Tail	Nose
		2	B	Tail	Nose	Tail	Nose
		3	A	Nose	Tail	Nose	Tail
		4	B	Nose	Tail	Nose	Tail

1. For actuators with H mounting and 50.8 mm (2-inch) output shafts, and for actuators with J mounting.

2. For conventional disk valves, use either valve shaft keyway.

3. See figure 6 for reference coupling orientation to use with this table.

4. When viewed from actuator side of valve.

5. For 60-degree rotation with PDTC action, the coupling and actuator output shaft assembly will be offset 30 degrees clockwise (for actuator housing construction style B) or counterclockwise (for actuator housing construction style A) in the lever when viewed from the splined end of the actuator shaft. 30 degrees is one spline tooth for 19.1 through 38.1 mm (3/8 through 1-1/2 inch) valve shafts.

A3251-1

Pressure Connections

1. If a positioner is used, the pressure connections to the actuator are normally made at the factory. Actuators without positioners should have either a 4-way solenoid valve or a switching valve connected to the pressure connections located at the top and bottom of the actuator cylinder.
2. Connect either pipe or tubing between the actuator pressure connections and the positioner or automatic controller. Keep the length of pipe or tubing as short as possible to avoid transmission lag in the control signal.

Table 6. Wrench Sizes Required for Actuator Adjustment, Inches

Actuator Size	Turnbuckle (Key 70)	Hex Nut (Key 11)	Hex Nut (Key 71)
30	1-1/8	3/4	1-1/8
40 & 60	1-5/16	1-1/8	1-5/16
68	1-7/8	1-1/8	1-7/8

3. When the actuator is completely installed and connected to the instrument, check for correct action (air-to-open or air-to-close) to match the controlling instrument. For successful operation, the actuator stem and operating shaft must move freely in response to the loading pressure change on the piston.

Adjustment

WARNING

Perform the steps in the **WARNING** at the beginning of the Maintenance section.

The only adjustment on the 1061 actuator is to make sure that the valve or other operated equipment is correctly closed when the actuator piston is against the travel stop. For accurate adjustment, the valve or other operated equipment must be removed from the pipeline.

If the actuator is equipped with an auxiliary manual handwheel actuator, make sure that the manual actuator is disengaged from the operated shaft and that the bypass valve (key 68, figure 8) is closed before performing adjustment procedures.

Perform the following steps to adjust the actuator turnbuckle. A regulated air supply will be required to stroke the actuator during this procedure. Also, when performing adjustment, refer to table 6 for the sizes of open-end wrenches required to loosen and tighten the hex nuts and turnbuckle. Key numbers referenced in this procedure are shown in figure 6.

1. Remove the access plate (key 72). Also remove the machine screws (key 73) if present.

Note

The cover (key 34) supports the outer end of the output shaft and should not be removed during actuator adjustment.

2. Stroke the actuator until the lower hex nut (key 11) can be reached through the access opening. Loosen the hex nut.
3. Stroke the actuator until the left-hand threaded upper hex nut (key 71) can be reached through the access opening. Loosen the hex nut.

4. Perform one of the following:
 - a. For push-down-to-close action (extending piston rod closes operated equipment)-- Slowly stroke the actuator to the down travel stop. Consult the appropriate instruction manual for determining the closed position of the valve or other operated equipment. Adjust the turnbuckle (key 70) until the closed position is reached. Lock this adjustment with the left-hand threaded hex nut (key 71). Stroke the actuator to the up travel stop, and tighten the lower hex nut (key 11). Tighten each hex nut to the torque value listed in table 7.
 - b. For push-down-to-open action (extending piston rod opens operated equipment)-- Stroke the actuator to the up travel stop. Consult the appropriate instruction manual for determining the closed position of the valve or other operated equipment. Check the valve position with respect to its properly closed position. Stroke the actuator until the turnbuckle (key 70) can be reached through the access opening. Adjust the linkage. Stroke the actuator to the up travel stop again, and check the new adjustment. Continue this procedure until the operated equipment is in the closed position when the actuator piston is resting against the up travel stop. Tighten the lower hex nut (key 11). Stroke the actuator down, and tighten the left-hand threaded hex nut (key 71). Tighten each hex nut to the torque value listed in table 7.
5. Replace the access plate (key 72) and install the machine screws (key 73) if used.

Note

Skip the following step if an auxiliary handwheel actuator is mounted on the 1061 actuator.

6. Loosen the self-tapping screws (key 39), and adjust the travel indicator (key 38). Retighten the self-tapping screws.

CAUTION

If using a handwheel actuator, the splines of the 1061 actuator shaft could be damaged if excessive torque is applied to the shaft by the manual actuator while the 1061 actuator is stopped at either end of travel. To protect the shaft, perform the travel stop adjustment procedure found in the separate handwheel actuator instruction manual.

Principle of Operation

Piston movement is accomplished by loading air pressure on one side of the piston, and unloading air pressure from the other side of the piston. If no positioner is used, a loading device, such as a 4-way switching valve, must be provided. Such a device is not furnished as part of the actuator.

Consult the separate positioner instruction manual for the 1061 actuator principle of operation with positioner.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions. Instructions are given below for disassembly and replacement of parts.

⚠ WARNING

Avoid personal injury or property damage from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Disassembly

The following procedure describes how the actuator can be disassembled for inspection and replacement of parts. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job. Key numbers referenced in this procedure are shown in figure 6 unless otherwise specified.

1. Bypass the valve or other operated equipment. Relieve all actuator loading pressure, and remove the tubing or pipe from the top of the actuator.
2. Remove the positioner, if one is used.
3. Mark the orientation of the travel indicator (key 38) with respect to the travel indicator scale (key 36). Then, unscrew the cap screws and washers (keys 35 and 76), and remove the cover (key 34). If a manual handwheel actuator is used, it will be removed with the cover.
4. Remove the retaining ring (key 31), and slide the hub (key 30) from the cover (key 34) or, if a manual handwheel actuator is used, remove the cover from the manual handwheel actuator connector. If disassembly of the manual handwheel actuator is required, refer to the separate manual actuator instruction manual for instructions.
5. Check the condition of the bearing (key 32). If replacement of the bearing is necessary, the travel indicator scale (key 36) must first be removed by removing the self-tapping screws (key 37). Mark the orientation of the travel indicator scale on the cover before removing it.

CAUTION

Do not use a hammer or similar tool to drive the lever (key 28) off the output shaft. Driving the lever could damage operated equipment. For valves, driving the lever could move the valve disk and bearings away from the centered position causing subsequent damage to valve parts.

If necessary, use a wheel puller to remove the lever. It is permissible to tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could damage the operated equipment.

6. For an actuator with an H mounting adaptation and a 22.2 through 38.1 mm (7/8 through 1-1/2 inch) output shaft, unscrew the cap screws (key 87) and remove the actuator from the operated equipment. Mark the orientation of the lever (key 28) with respect to the output shaft (key 94). This marking is used during reassembly to allow for proper lever/output shaft positioning. Then, loosen the cap screw (key 29) so that the output shaft is free to slide off the lever. With the lever and output shaft properly marked, unscrew the cap screws (key 24) and remove the

mounting plate (key 23) and output shaft (key 94) assembly from the actuator housing (key 21). If necessary, remove the retaining ring (key 95) and separate the output shaft from the mounting plate. For 50.8 mm (2-inch) output shafts, refer to step 7 for this procedure.

7. For an actuator with either a J mounting adaptation (see figure 6), or an H mounting adaptation with a 50.8mm (2-inch) output shaft (see figure 7), proceed as follows:

Remove the cap screws (key 87, not shown in figure 6) and remove the actuator from the operated equipment. For an actuator with J mounting and a 31.8 or 38.1 mm (1-1/4 or 1-1/2 inch) valve shaft diameter, two spacers (key 99, not shown in figure 6) are also removed with the cap screws (key 87). When separating the output shaft (key 94) and coupling (key 97) from the operated shaft, remember to remove the woodruff key (key 98, not shown in figure 7) from the operated shaft keyway. Mark the orientation of the lever (key 28, figure 6) with respect to the output shaft (key 94). This marking is used during reassembly to allow for proper lever/output shaft positioning. Then, loosen the cap screw (key 29, figure 6) so that the output shaft is free to slide off the lever. With the lever and output shaft properly marked, unscrew the cap screws (key 24) and remove either the mounting yoke (key 23, figure 6 for J mounting) or the mounting plate (key 23, figure 7 for H mounting) plus the attached output shaft (key 94) from the actuator housing (key 21). If necessary, remove the retaining ring (key 95) and slide the mounting yoke or mounting plate off the output shaft.

8. Check the bearing (key 81) in the mounting yoke or the mounting plate (key 23). Press out and replace the bearing if necessary.
9. Heat the hex nut (key 14) to 177°C (350°F) long enough for the thread-locking adhesive (medium strength (key 92) to lose its holding strength. Then, remove the cap screw and hex nut (keys 13 and 14), and remove the lever (key 28) from the housing.
10. Remove the rod end bearing and the hex nut (keys 12 and 11), and then the turnbuckle and the hex nut (keys 70 and 71).
11. For size 30, 40, and 68 actuators only, unscrew the cap screws (key 6) and remove the cylinder cap (key 4). Inspect and, if necessary, replace the O-ring (key 5).
12. Remove the cap screws (key 3) and slide the cylinder assembly (key 1) from the cylinder flange (key 2).
13. Pull the piston (key 7) and the piston rod (key 10) from the cylinder assembly.
14. Check and, if necessary, replace the O-rings (keys 8 and 16).
15. To separate the piston (key 7) from the piston rod (key 10), unscrew the cap screw to hex nut (key 9) and remove the washer (key 77).
16. Unscrew the cap screws (key 22) and remove the cylinder flange (key 2), the sliding seal (key 19), and the seal support cylinder (key 20). For actuators with 60-degree rotation, a travel stop (key 15) will also be removed with these parts.
17. Check and, if necessary, replace the O-rings (keys 17 and 18) and the thrust washer (key 74).

Assembly

1. Apply lithium grease (key 93) to the surfaces of the sliding seal (key 19). Then, install the seal support cylinder (key 20), the thrust washer (key 74), the sliding seal, and the cylinder flange (key 2) and secure these parts with the cap screws (key 22). Tighten the cap screws to the torque value listed in table 7. For actuators with 60-degree rotation, a travel stop (key 15) will be threaded into the cylinder flange.
2. Apply lithium grease (key 93) to the cylindrical surface of the piston rod (key 10) and apply anti-seize sealant (key 91) to the tapered end of the piston rod. Attach the piston and washer (keys 7 and 77) to the piston rod, and secure them with the cap screw or hex nut (key 9). Tighten the cap screw or hex nut to the torque value listed in table 7.
3. Insert the piston and piston rod assembly down through the sliding seal (key 19). Attach the hex nut (key 71), the turnbuckle (key 70), the hex nut (key 11), and the rod end bearing (key 12) to the piston rod assembly. Tighten both hex nuts to the torque value listed in table 7.
4. Apply lithium grease (key 93) to the inside wall of the cylinder, and then attach the cylinder assembly (key 1) to the cylinder flange with the cap screws (key 3). For size 30, 40, and 68 actuators only, replace the cylinder cap (key 4),

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

Instruction Manual

D100325X012

1061 H & J Actuator

June 2017

and secure it to the cylinder assembly with the cap screws (key 6). Tighten all cap screws to the torque value listed in table 7.

5. If the bearing (key 81) was removed, press in the new bearing. The end of the bearing should be flush with the outside of the mounting yoke or mounting plate (key 23).
6. For an actuator with an H mounting adaptation and a 22.2 through 38.1 mm (7/8 through 1-1/2 inch) output shaft, install the output shaft (key 94) through the mounting plate (key 23) and secure it with the retaining ring (key 95). Then, attach the mounting plate and output shaft assembly to the actuator housing (key 21) with the cap screws (key 24). Tighten the cap screws to the appropriate torque value listed in table 7.
7. For an actuator with an H mounting adaptation and a 50.8mm (2-inch) output shaft, refer to figure 7. Install the output shaft (key 94) with attached coupling (key 97) through the mounting plate (key 23) and secure it with the retaining ring (key 95). Attach the mounting plate and output shaft assembly to the actuator housing with the cap screws (key 24). Tighten the cap screws to the appropriate torque value listed in table 7.

Table 7. Bolting Torques

KEY NUMBER	SIZE 30		SIZE 40 & 60		SIZE 68	
	N•m	Lbf•ft	N•m	Lbf•ft	N•m	Lbf•ft
3	102	75	102	75	102	75
6	14	10	14	10	14	10
9	61	45	136	100	248	257
11	34	25	102	75	102	75
13	81	60	271	200	271	200
22	23	17	68	50	68	50
24	34	25	81	60	81	60
29	81	60	271	200	271	200
35	34	25	81	60	81	60
41	14	10	14	10	14	10
71	102	75	163	120	253	260

8. For an actuator with a J mounting adaptation, refer to figure 6. Install the output shaft (key 94) with attached coupling (key 97) through the mounting yoke (key 23) and secure it with the retaining ring (key 95). Attach the mounting yoke and output shaft assembly to the actuator housing (key 21) with the cap screws (key 24). Tighten the cap screws to the appropriate torque value listed in table 7.
9. Apply lithium grease (key 93) to the output shaft splines. Then, align the lever (key 28) and output shaft so that the marking that was made in step 6 or 7 of the disassembly procedure is oriented correctly. Slide the lever into place. When installing the lever, align the bolt holes in the lever as close as possible with the hole in the rod end bearing (key 12). Temporarily rotate the lever and output shaft until the rod end bearing no longer interferes with further installation of the lever. Then, slide the lever as far as it can go onto the output shaft.
10. Clamp the lever to the output shaft with the cap screw (key 29). Tighten the cap screw to the torque value listed in table 7.
11. Rotate the lever to align with the rod end bearing (key 12). This connection can be aided by carefully stroking the actuator with a regulated air source.
12. Apply thread-locking adhesive (medium strength) (key 92) to the threads of the cap screw (key 13). Then, connect the lever and the rod end bearing with the cap screw and hex nut (keys 13 and 14). Tighten the cap screw to the torque value listed in table 7.
13. If a positioner is used, consult the separate positioner instruction manual for proper installation.
14. Install the hub (key 30) and the bearing (key 32) into the cover (key 34), and secure them with the retaining ring (key 31).
15. Install the travel indicator scale (key 36) so that the markings on the scale and cover that were made in step 5 of the disassembly procedure are oriented correctly. Secure the travel indicator scale to the cover with the self-tapping screws (key 37). Then install the travel indicator (key 38), and secure it with the self-tapping screws (key 39).
16. Note the position of the valve or other operated equipment and the direction of rotation.
 - a. If no handwheel actuator is used, position the travel indicator (key 38) so that the markings on the travel indicator and travel indicator scale that were made in step 3 of the disassembly procedure are oriented correctly.

Then, replace the cover (key 34) and secure it with the cap screws and washers (key 35 and 76). If the holes in the cover and housing do not align, temporarily loosen the cap screws (key 24) and shift the housing slightly. Tighten the cap screws to the torque value listed in table 7.

- b. If the actuator is equipped with a manual handwheel actuator, refer to the separate instruction manual for mounting instructions.

17. Follow the instructions in the Actuator Mounting portion of the Installation section for correct actuator mounting and adjustment. Remember to replace the access plate (key 72) when performing these procedures.

Changing Actuator Mounting

The actuator is normally positioned vertically in a horizontal pipeline. However, there are two possible mounting styles and four possible positions for each style (see figure 4). Key numbers referenced in the following procedures are shown in figure 6 unless otherwise specified.

⚠ WARNING

Perform the steps in the WARNING at the beginning of the Maintenance section.

Use the following procedures along with figure 6 for key number references to convert from style A to style B or vice-versa or to change the mounting position.

Changing Styles

1. Unscrew the cap screws and washers (key 35 and 76), and remove the cover (key 34). If an optional manual handwheel actuator is used, it will be removed with the cover.
2. Heat the hex nut (key 14) to 177°C (350°F) long enough for the thread locking adhesive (medium strength) (key 92) to lose its holding strength. Then, remove the cap screw and hex nut (keys 13 and 14).
3. Loosen the cap screw (key 29).

CAUTION

Do not use a hammer or similar tool to drive the lever (key 28) off the output shaft. Driving the lever could damage operated equipment. For valves, driving the lever could move the valve disk and bearings away from the centered position causing subsequent damage to valve parts.

If necessary, use a wheel puller to remove the lever. It is permissible to tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could damage the operated equipment.

4. Mark the side of the lever (key 28) that is nearest to the end of the output shaft (key 94). This marking is used during reassembly to determine which side of the lever should be inserted into the actuator housing first. When the lever is marked, remove the lever.
5. For an actuator with a J mounting adaptation,
 - a. Unscrew the cap screws (key 24), and remove the actuator housing (key 21) from the mounting yoke (key 23).
 - b. Rotate the actuator housing 180 degrees, maintaining the appropriate position (1, 2, 3, or 4), and place the actuator onto the mounting yoke (key 23).

- c. Secure the actuator housing to the mounting yoke with the cap screws (key 24). Tighten the cap screws to the torque value listed in table 7.
6. For an actuator with an H mounting adaptation,
 - a. Unscrew the cap screws (key 87) and remove the actuator assembly from its mounting bracket.
 - b. Unscrew the cap screws (key 24) and remove the mounting plate (key 23) and output shaft (key 94) assembly from the actuator housing. Remount the assembly on the opposite side of the actuator, and secure it to the housing with the cap screws (key 24). Tighten the cap screws to the torque value listed in table 7.
 - c. Rotate the actuator housing 180 degrees, maintaining the appropriate position (1, 2, 3, or 4) and secure the actuator housing to the mounting bracket with the cap screws (key 87). Tighten the cap screws to the torque value listed in table 7.
7. Install the lever (key 28) as follows:
 - a. For push-down-to-open action, rotate the operated equipment to the fully closed position.
 - b. For push-down-to-close action, rotate the operated equipment to the fully open position.
 - c. With the operated equipment oriented correctly, slide the lever onto the output shaft (key 94) with the end marked in step 4 inserted first. When installing the lever, align the bolt holes in the lever as close as possible with the hole in the rod end bearing (key 12).
 - d. Temporarily rotate the lever and output shaft until the rod end bearing no longer interferes with further installation of the lever. Then, slide the lever as far as it can go onto the output shaft. Clamp the lever to the output shaft with the cap screw (key 29). Tighten the cap screw to the torque value listed in table 7.
 - e. Rotate the lever and output shaft back to the original position (i.e., operated equipment fully closed for push-down-to-open action or operated equipment fully open for push-down-to-close action). Then, adjust the rod end bearing so that it can be attached to the lever.
8. Apply thread-locking adhesive (medium strength) (key 92) to the threads of the cap screw (key 13).
9. Connect the lever (key 28) and the rod end bearing (key 12) with the cap screw and hex nut (keys 13 and 14). This connection can be aided by stroking the actuator from its up travel stop with a regulated air source. Tighten the cap screw to the torque value listed in table 7.
10. Note the position of the valve or other operated equipment and direction of rotation.
 - a. Position the travel indicator (key 38) accordingly. Replace the cover (key 34), and secure it with the cap screws and washers (keys 35 and 76). If the holes in the cover and housing (key 21) do not align, use a regulated air source to move the actuator slightly off the up travel stop. If hole alignment cannot be obtained in this manner, temporarily loosen the cap screws (key 24), and shift the housing slightly. Do not stroke the actuator while the cover is off. Tighten both sets of cap screws to the torque values listed in table 7.
 - b. If a manual handwheel actuator is used, refer to the separate instruction manual for mounting instructions.
11. Follow the instructions in the Adjustment section for turnbuckle adjustment.

Changing Positions

1. Unscrew the cap screws and washers (keys 35 and 76), and remove the cover (key 34). If an optional manual handwheel actuator is used, it will be removed with the cover.
2. Mark the orientation of the lever (key 28) with respect to the output shaft (key 94). This marking is used during reassembly to allow for proper lever/output shaft positioning. When the lever and output shaft are properly marked, heat the hex nut (key 14) to 177°C (350°F) long enough for the thread locking adhesive (medium strength) (key 92) to lose its holding strength. Then, remove the cap screw and hex nut (keys 13 and 14).

CAUTION

Do not use a hammer or similar tool to drive the lever (key 28) off the output shaft. Driving the lever could damage operated equipment. For valves, driving the lever could move the valve disk and bearings away from the centered position causing subsequent damage to valve parts.

If necessary, use a wheel puller to remove the lever. It is permissible to tap the wheel puller screw lightly to loosen the lever, but hitting the screw with excessive force could damage the operated equipment.

3. Loosen the cap screw (key 29) and remove the lever (key 28) from the output shaft (key 94).
4. For an actuator with a J mounting adaptation,
 - a. Unscrew the cap screws (key 24), and remove the actuator housing (key 21) from the mounting yoke (key 23).
 - b. Rotate the actuator housing to the new position (1, 2, 3, or 4).
 - c. Secure the actuator housing to the mounting yoke with the cap screws (key 24). Tighten the cap screws to the torque value listed in table 7.
5. For an actuator with an H mounting adaptation,
 - a. Unscrew the cap screws (key 87) and loosen the actuator assembly from its mounting bracket.
 - b. Rotate the actuator housing to the new position (1, 2, 3, or 4).
 - c. Secure the actuator housing to the mounting bracket with the cap screws (key 87). Tighten the cap screws to the torque value listed in table 7.
6. Referring to the alignment marks that were made in step 2, install the lever (key 28) onto the output shaft (key 94) as follows:
 - a. If the new actuator position is 90 degrees clockwise from the previous actuator position, install the lever so that its orientation mark is located 90 degrees clockwise from the mark on the output shaft.
 - b. If the new actuator position is 90 degrees or 180 degrees counterclockwise from the previous position, install the lever so that its orientation mark is located either 90 degrees (for 90 degrees) or 180 degrees (for 180 degrees) counterclockwise (respectively) from the mark on the output shaft.
 - c. Slide the lever onto the output shaft with the bolt holes in the lever aligned as closely as possible with the hole in the rod end bearing (key 12). Then, temporarily rotate the lever and output shaft until the rod end bearing no longer interferes with further installation of the lever, and slide the lever as far as it can go onto the output shaft. Clamp the lever to the output shaft with the cap screw (key 29). Tighten the cap screw to the torque value listed in table 7.
 - d. Rotate the lever and output shaft back to the original position, and then adjust the rod end bearing so that it can be attached to the lever.
7. Apply thread-locking adhesive (medium strength) (key 92) to the threads of the cap screw (key 13).
8. Connect the lever (key 28) and the rod end bearing (key 12) with the cap screw and hex nut (keys 13 and 14). This connection can be aided by stroking the actuator from its up travel stop with a regulated air source. Tighten the cap screw to the torque value listed in table 7.
9. Note the position of the valve or other operated equipment and direction of rotation.
 - a. Position the travel indicator (key 38) accordingly. Replace the cover (key 34), and secure it with the cap screws and washers (keys 35 and 76). If the holes in the cover and housing (key 21) do not align, use a regulated air

source to move the actuator slightly off the up travel stop. If hole alignment cannot be obtained in this manner, temporarily loosen the cap screws (key 24), and shift the housing slightly. Do not stroke the actuator while the cover is off. Then, tighten both sets of cap screws to the torque values listed in table 7.

b. If a manual handwheel actuator is used, refer to the separate instruction manual for mounting instructions.

10. Follow the instructions in the Adjustment section for turnbuckle adjustment.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner about this equipment, refer to the serial number found on the actuator nameplate (key 42, figure 6).

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

Scope of Manual

This instruction manual includes installation, operation, and maintenance information for the Fisher 1078 declutchable manual actuator (figure 1). Refer to separate instruction manuals for instructions covering the power actuator and control valve.

Do not install, operate, or maintain a 1078 declutchable manual actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) or Local Business Partner before proceeding.

Table 1. Specifications

Available Configurations Direct and reverse acting; see Handwheel Rotation in this specification table Actuator Sizes See tables 2, 3, and 4 Acceptable Coupling Shaft Diameters See tables 2, 3, and 4 Power Actuator Compatibility See tables 2, 3, and 4 Output Torque See tables 2, 3, and 4 Wheel-Rim Force See tables 2, 3, and 4 Handwheel Turns Required For Full Rotation See tables 2, 3, and 4 Handwheel Rotation Direct Acting Construction: Clockwise handwheel rotation closes the valve (produces clockwise valve shaft rotation) Reverse Acting Construction: Clockwise handwheel rotation closes the valve (produces counterclockwise valve shaft rotation) Decide whether Direct or Reverse Action is required by referring to the appropriate valve or power actuator instruction manual and determining valve rotation. ---	---

1. If a positioner is used, the right-hand or left-hand mounting option will be limited to the side away from the positioner.

Description

The 1078 manual actuator, shown in figures 1 and 2, is a declutchable unit for manual operation of control valves and equipment that use power actuators. The 1078 manual actuator mounts directly to Fisher 1052 size 70; 1061 sizes 30, 40, 60, 68, 80, and 100; and to all sizes of 2052 actuators. The 1078 manual actuator can be engaged to allow manual operation of the valve when the power actuator is not in use. It can be disengaged to allow automatic operation of the valve by the power actuator. The mechanism used allows manual actuator engagement at any point of power actuator rotation.

Figure 2. Fisher 1078 Declutchable Manual Actuator Mounted on a 2052 Size 1 Actuator and V300 Valve with FIELDVUE™ DVC6200 Digital Valve Controller

X0177

Specifications

1078 manual actuator specifications are given in table 1. Specifications for a control valve assembly as it comes from the factory appear on a nameplate attached to the power actuator.

II-FA (60,000 in.lbs)	54, 63.5	2-1/8, 2-1/2	1061	80, 100	288:1 ⁽²⁾	406	16	6301	55,762	400	90	Divide N•m req'd by 15.7	Divide lbf•in req'd by 619	48	72
1. Compare table value with torque requirements of the valve plus the torque required to compress the power actuator spring (from Fisher Catalog 14). Note that dynamic torque of the valve may have a positive or negative effect on total torque required. 2. Has spur gear. 3. 2A 3/4 inch shaft will also mount on the 1061 size 40, 60, and 68. 4. Maximum torque of connection between power and manual actuator.															

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

The 1078 manual actuator is normally shipped mounted on a power actuator. If the manual actuator has been shipped separately for installation on a power actuator, or if the manual actuator was removed for maintenance, mount the manual actuator by following the instructions presented in this section.

Converting An Existing Power Actuator For Use With The Fisher 1078 Manual Actuator

Field conversion of a power actuator for use with the 1078 manual actuator may require replacement and/or removal of some parts. The procedures which follow apply only to power actuators which were not ordered specifically for use with the 1078 manual actuator. Proceed as appropriate:

Installing the Manual Actuator

⚠ WARNING

Avoid personal injury from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
 - Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
 - Disconnect any operating lines providing air pressure, electric power, or a control signal to the power actuator. Be sure the actuator cannot suddenly open or close the valve.
 - Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
 - Vent the power actuator loading pressure and relieve any actuator spring precompression.
 - Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
 - The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
 - Check with your process or safety engineer for any additional measures that must be taken to protect against process media.
-

CAUTION

Undertravel or overtravel of the valve ball or disk, especially at the closed position, may result in poor valve performance and/or damage to the equipment. Make certain that the power actuator travel stops are properly set before installing and adjusting the manual actuator. Refer to the instruction manuals for the valve and the power actuator for information about setting travel stops.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Also shut off all pressure lines to the power actuator and release all

pressure from the power actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

2. Make certain that the power actuator travel stops have been properly set according to the caution given above.
3. For spring-return power actuators, allow the power actuator to remain in the position where the spring is relaxed. For double-acting power actuators, apply supply pressure as appropriate to position the valve disk or ball in either the open or closed position.
4. Note whether the valve disk or ball is in the open or closed position.
5. Rotate the handwheel to move the drive sleeve gear and travel indicator to the position that corresponds with the position of the valve disk or ball. For both direct and reverse acting manual actuators, clockwise handwheel rotation sets the manual actuator to the closed position. Counterclockwise handwheel rotation sets the manual actuator to the open position.

Installing the Manual Actuator on a 1061 Size 30, 40, 60, 68, 80, or 100 and 1052 Size 70

For manual actuator installation on 1061 sizes 30, 40, 60, 68, 80, and 100; and 1052 size 70, remove the actuator cover (key 34) and attached parts from 1061 or 1052. Replace with 1078. Most assemblies require installation of a new lever and splined adaptor to complete the installation. When used, the splined adaptor slides inside the new lever and the lever is then clamped onto the splined adaptor. See figure 5.

1. Remove the lever and add a new lever and splined adaptor when needed. See figure 5.

The splined adaptor slides inside the new lever and the lever is then clamped onto the splined adaptor.

2. Disengage the manual actuator.
3. Install the manual actuator.
4. Tighten the cap screws to the final torque value.
5. For double-acting power actuators, be certain the power actuator is equipped with a bypass valve. Operating the handwheel mechanism against the force of differential cylinder pressures will be difficult or impossible.

Installing the Manual Actuator on a 2052 Size 1, 2, or 3

1. Remove the travel scale and travel indicator. They will no longer be required since the 1078 has it's own scale and indicator.
2. Mount the manual actuator on the surface where the travel scale was.
3. Position the manual actuator on the 2052 so that the drive square fits into the quad square spline of the 2052 lever.
4. Bolt the manual actuator onto the 2052.

Operation

After the travel indicator pointer has been adjusted and the control valve assembly installed, the manual actuator is ready for operation.

CAUTION

Applying too much torque to the actuator and valve parts could cause damage to the parts. To avoid such damage, do not exceed the maximum allowable torques listed in table 2, 3, or 4 or any other torque limitation of internal valve parts. Also, do not use wrenches or other devices on the handwheel or handwheel shaft to increase operating force.

If the force required to rotate the handwheel exceeds the wheel-rim force listed in tables 2, 3, and 4, refer to the maintenance procedure.

Engaging and Disengaging the Manual Actuator

Engaging the Manual Actuator

1. Shut off the supply pressure to the power actuator.
2. Pull the ring on the detent mechanism to unlock the lever. Move the lever into the engaged position until it is against the stop pin and locked in position by the detent mechanism. (Note that stop pins are not available on 1078 size II-FA actuators.)
3. If applicable, open the power actuator bypass valve.

Disengaging the Manual Actuator

CAUTION

Disengaging the manual actuator when forces such as spring compression, cylinder pressure, and dynamic torque are present may cause sudden, extreme movement of all control valve components. This can result in damage to equipment and violent disturbance of the process. Before disengaging the manual actuator, take appropriate steps to ensure that the return to automatic operation will not result in an extreme repositioning of control valve components. Procedures to determine approximate system balance are given in the following steps.

1. Before disengaging the manual actuator, approximate system balance should be achieved. The system is in balance when the actual valve ball or disk position is approximately the same as the position requested by the automatic control system. Under balanced system conditions, the manual actuator disengaging lever moves freely without use of excessive force. If after releasing the detent mechanism, the lever does not move freely toward the disengaged position, some system force is causing an imbalance. A forced return to automatic operation under these conditions can cause serious damage to the equipment and violent disturbance of the process.
2. If possible, determine whether the automatic control system is tending to open or close the valve ball or disk, and rotate the handwheel in the appropriate direction until friction in the manual operator is reduced and the lever can be easily moved by hand. As an alternate approach, local manipulation of the supply pressure to the power actuator may bring the set point of the automatic system closer to the actual valve ball or disk position.
3. If a smooth transition from manual to automatic operation cannot be ensured, isolate the valve from the process. Position the manual actuator so that it matches the position of the ball or disk when no supply pressure is applied to the power actuator.
4. Pull the ring on the detent mechanism to unlock the lever. Push the lever into the disengaged position until it is against the stop pin and locked in position by the detent mechanism. (Note that stop pins are not available on 1078 size II-FA actuators.)
5. Close the bypass valve and return supply pressure to the power actuator.

Maintenance

If the force required to rotate the handwheel exceeds the wheel-rim force listed in tables 2, 3, and 4, check for the following conditions:

- Insufficient lubrication,
- Seized actuator parts,

- Excessive pressure drop across the valve body, or
- Obstruction to the valve disk or ball rotation.

If the manual actuator does not seem to control the process fluid, the worm or drive sleeve gear teeth may be broken, the pin (key 3) may be sheared, or the internal power actuator or valve parts may be broken. Purchase a replacement manual actuator if necessary. Refer to the power actuator and valve instruction manuals if power actuator or valve maintenance is needed.

Lubrication

The interior parts of the 1078 manual actuator should be lubricated on a regular schedule with a quality gear lubricant. The interior parts should also be lubricated whenever difficulty in handwheel rotation indicates a need for lubrication.

⚠ WARNING

Avoid personal injury from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- **Do not remove the actuator from the valve while the valve is still pressurized.**
- **Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.**
- **Disconnect any operating lines providing air pressure, electric power, or a control signal to the power actuator. Be sure the actuator cannot suddenly open or close the valve.**
- **Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.**
- **Vent the power actuator loading pressure and relieve any actuator spring precompression.**
- **Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.**
- **The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.**
- **Check with your process or safety engineer for any additional measures that must be taken to protect against process media.**

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. Mark the position of the travel indicator pointer on the indicator dial. The travel indicator pointer must be returned to its original position when assembling the manual actuator. Remove the machine screws and the travel indicator pointer.
3. Remove the manual actuator cover screws.
4. Remove the travel indicator scale and the gearbox cover plate. Coat the worm, the drive sleeve gear teeth, and the bearing surfaces of the gearbox housing and worm with a quality gear lubricant.
5. Install the cover plate and the travel indicator scale on the gearbox.
6. Replace the manual actuator cover screws.

Parts Ordering

When corresponding with your [Emerson sales office](#) or Local Business Partner, indicate the type number and size of the power actuator and the mounting adaptation used. If the manual actuator was shipped separately (not attached to a power actuator), give the serial number of the unit, which is shown on a tag attached to the manual actuator.

For 1052 (size 70), and 1061 (sizes 30, 40, 60, 68, 80, and 100), indicate valve shaft size.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson Automation Solutions should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

Scope of Manual

This instruction manual includes installation, operation, and maintenance information for the Fisher 1078 declutchable manual actuator (figure 1). Refer to separate instruction manuals for instructions covering the power actuator and control valve.

Do not install, operate, or maintain a 1078 declutchable manual actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Table 1. Specifications

---	---

1. If a positioner is used, the right-hand or left-hand mounting option will be limited to the side away from the positioner.

Description

The 1078 manual actuator, shown in figures 1 and 2, is a declutchable unit for manual operation of control valves and equipment that use power actuators. The 1078 manual actuator mounts directly to Fisher 1052 size 70; 1061 sizes 30, 40, 60, 68, 80, and 100; and to all sizes of 2052 actuators. The 1078 manual actuator can be engaged to allow manual operation of the valve when the power actuator is not in use. It can be disengaged to allow automatic operation of the valve by the power actuator. The mechanism used allows manual actuator engagement at any point of power actuator rotation.

Figure 2. Fisher 1078 Declutchable Manual Actuator Mounted on a 2052 Size 1 Actuator and V300 Valve with FIELDVUE™ DVC6200 Digital Valve Controller

X0177

Specifications

1078 manual actuator specifications are given in table 1. Specifications for a control valve assembly as it comes from the factory appear on a nameplate attached to the power actuator.

1. Compare table value with torque requirements of the valve plus the torque required to compress the power actuator spring (from Fisher Catalog 14). Note that dynamic torque of the valve may have a positive or negative effect on total torque required. 2. Has spur gear. 3. 2A 3/4 inch shaft will also mount on the 1061 size 40, 60, and 68. 4. Maximum torque of connection between power and manual actuator.															

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

The 1078 manual actuator is normally shipped mounted on a power actuator. If the manual actuator has been shipped separately for installation on a power actuator, or if the manual actuator was removed for maintenance, mount the manual actuator by following the instructions presented in this section.

Converting An Existing Power Actuator For Use With The Fisher 1078 Manual Actuator

Field conversion of a power actuator for use with the 1078 manual actuator may require replacement and/or removal of some parts. The procedures which follow apply only to power actuators which were not ordered specifically for use with the 1078 manual actuator. Proceed as appropriate:

Installing the Manual Actuator

⚠ WARNING

Avoid personal injury from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
 - Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
 - Disconnect any operating lines providing air pressure, electric power, or a control signal to the power actuator. Be sure the actuator cannot suddenly open or close the valve.
 - Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure on both sides of the valve. Drain the process media from both sides of the valve.
 - Vent the power actuator loading pressure and relieve any actuator spring precompression.
 - Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
 - The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
 - Check with your process or safety engineer for any additional measures that must be taken to protect against process media.
-

NOTICE

Undertravel or overtravel of the valve ball or disk, especially at the closed position, may result in poor valve performance and/or damage to the equipment. Make certain that the power actuator travel stops are properly set before installing and adjusting the manual actuator. Refer to the instruction manuals for the valve and the power actuator for information about setting travel stops.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Also shut off all pressure lines to the power actuator and release all

pressure from the power actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

2. Make certain that the power actuator travel stops have been properly set according to the caution given above.
3. For spring-return power actuators, allow the power actuator to remain in the position where the spring is relaxed. For double-acting power actuators, apply supply pressure as appropriate to position the valve disk or ball in either the open or closed position.
4. Note whether the valve disk or ball is in the open or closed position.
5. Rotate the handwheel to move the drive sleeve gear and travel indicator to the position that corresponds with the position of the valve disk or ball. For both direct and reverse acting manual actuators, clockwise handwheel rotation sets the manual actuator to the closed position. Counterclockwise handwheel rotation sets the manual actuator to the open position.

Installing the Manual Actuator on a 1061 Size 30, 40, 60, 68, 80, or 100 and 1052 Size 70

For manual actuator installation on 1061 sizes 30, 40, 60, 68, 80, and 100; and 1052 size 70, remove the actuator cover (key 34) and attached parts from 1061 or 1052. Replace with 1078. Most assemblies require installation of a new lever and splined adaptor to complete the installation. When used, the splined adaptor slides inside the new lever and the lever is then clamped onto the splined adaptor. See figure 5.

1. Remove the lever and add a new lever and splined adaptor when needed. See figure 5.

The splined adaptor slides inside the new lever and the lever is then clamped onto the splined adaptor.

2. Disengage the manual actuator.
3. Install the manual actuator.
4. Tighten the cap screws to the final torque value.
5. For double-acting power actuators, be certain the power actuator is equipped with a bypass valve. Operating the handwheel mechanism against the force of differential cylinder pressures will be difficult or impossible.

Installing the Manual Actuator on a 2052 Size 1, 2, or 3

1. Remove the travel scale and travel indicator. They will no longer be required since the 1078 has it's own scale and indicator.
2. Mount the manual actuator on the surface where the travel scale was.
3. Position the manual actuator on the 2052 so that the drive square fits into the quad square spline of the 2052 lever.
4. Bolt the manual actuator onto the 2052.

Operation

After the travel indicator pointer has been adjusted and the control valve assembly installed, the manual actuator is ready for operation.

NOTICE

Applying too much torque to the actuator and valve parts could cause damage to the parts. To avoid such damage, do not exceed the maximum allowable torques listed in table 2, 3, or 4 or any other torque limitation of internal valve parts. Also, do not use wrenches or other devices on the handwheel or handwheel shaft to increase operating force.

If the force required to rotate the handwheel exceeds the wheel-rim force listed in tables 2, 3, and 4, refer to the maintenance procedure.

Engaging and Disengaging the Manual Actuator

Engaging the Manual Actuator

1. Shut off the supply pressure to the power actuator.
2. Pull the ring on the detent mechanism to unlock the lever. Move the lever into the engaged position until it is against the stop pin and locked in position by the detent mechanism. (Note that stop pins are not available on 1078 size II-FA actuators.)
3. If applicable, open the power actuator bypass valve.

Disengaging the Manual Actuator

NOTICE

Disengaging the manual actuator when forces such as spring compression, cylinder pressure, and dynamic torque are present may cause sudden, extreme movement of all control valve components. This can result in damage to equipment and violent disturbance of the process. Before disengaging the manual actuator, take appropriate steps to ensure that the return to automatic operation will not result in an extreme repositioning of control valve components. Procedures to determine approximate system balance are given in the following steps.

1. Before disengaging the manual actuator, approximate system balance should be achieved. The system is in balance when the actual valve ball or disk position is approximately the same as the position requested by the automatic control system. Under balanced system conditions, the manual actuator disengaging lever moves freely without use of excessive force. If after releasing the detent mechanism, the lever does not move freely toward the disengaged position, some system force is causing an imbalance. A forced return to automatic operation under these conditions can cause serious damage to the equipment and violent disturbance of the process.
2. If possible, determine whether the automatic control system is tending to open or close the valve ball or disk, and rotate the handwheel in the appropriate direction until friction in the manual operator is reduced and the lever can be easily moved by hand. As an alternate approach, local manipulation of the supply pressure to the power actuator may bring the set point of the automatic system closer to the actual valve ball or disk position.
3. If a smooth transition from manual to automatic operation cannot be ensured, isolate the valve from the process. Position the manual actuator so that it matches the position of the ball or disk when no supply pressure is applied to the power actuator.
4. Pull the ring on the detent mechanism to unlock the lever. Push the lever into the disengaged position until it is against the stop pin and locked in position by the detent mechanism. (Note that stop pins are not available on 1078 size II-FA actuators.)
5. Close the bypass valve and return supply pressure to the power actuator.

Maintenance

If the force required to rotate the handwheel exceeds the wheel-rim force listed in tables 2, 3, and 4, check for the following conditions:

- Insufficient lubrication,
- Seized actuator parts,

- Excessive pressure drop across the valve body, or
- Obstruction to the valve disk or ball rotation.

If the manual actuator does not seem to control the process fluid, the worm or drive sleeve gear teeth may be broken, the pin (key 3) may be sheared, or the internal power actuator or valve parts may be broken. Purchase a replacement manual actuator if necessary. Refer to the power actuator and valve instruction manuals if power actuator or valve maintenance is needed.

Lubrication

The interior parts of the 1078 manual actuator should be lubricated on a regular schedule with a quality gear lubricant. The interior parts should also be lubricated whenever difficulty in handwheel rotation indicates a need for lubrication.

⚠ WARNING

Avoid personal injury from sudden release of process pressure or uncontrolled movement of parts. Before performing any maintenance operations:

- **Do not remove the actuator from the valve while the valve is still pressurized.**
- **Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.**
- **Disconnect any operating lines providing air pressure, electric power, or a control signal to the power actuator. Be sure the actuator cannot suddenly open or close the valve.**
- **Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.**
- **Vent the power actuator loading pressure and relieve any actuator spring precompression.**
- **Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.**
- **The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.**
- **Check with your process or safety engineer for any additional measures that must be taken to protect against process media.**

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. Mark the position of the travel indicator pointer on the indicator dial. The travel indicator pointer must be returned to its original position when assembling the manual actuator. Remove the machine screws and the travel indicator pointer.
3. Remove the manual actuator cover screws.
4. Remove the travel indicator scale and the gearbox cover plate. Coat the worm, the drive sleeve gear teeth, and the bearing surfaces of the gearbox housing and worm with a quality gear lubricant.
5. Install the cover plate and the travel indicator scale on the gearbox.
6. Replace the manual actuator cover screws.

Parts Ordering

When corresponding with your [Emerson sales office](#) indicate the type number and size of the power actuator and the mounting adaptation used. If the manual actuator was shipped separately (not attached to a power actuator), give the serial number of the unit, which is shown on a tag attached to the manual actuator.

For 1052 (size 70), and 1061 (sizes 30, 40, 60, 68, 80, and 100), indicate valve shaft size.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts List

Note

Contact your [Emerson sales office](#) or for Part Ordering information.

Manual Actuator Assembly (figures 3 and 4)

Key Description

1	Actuator
2	Handwheel
3	Pin

Note

A new lever and splined adaptor (figure 5) are needed on most assemblies for field installation of the 1078 onto the 1052 size 70, and 1061 sizes 30, 40, 60, 68, 80, & 100 actuators.

Key	Description
4	Travel Indicator scale
5	Travel Indicator Pointer
6	Machine Screw, steel (2 required)
9	Shaft Adaptor

Field Mounting Parts

For 1061; and 1052 Size 70 Actuators

Note

Most assemblies require installation of a new lever to complete the installation. Contact your Emerson sales office.

W6214

Introduction

Scope of Manual

This instruction manual includes installation, operation, and maintenance information for the Fisher 1079 declutchable manual actuator. Refer to separate instruction manuals for instructions covering the Hytork actuator and the control valve.

Do not install, operate, or maintain a 1079 manual actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Table 1. Specifications

Available Configurations	Standard Mounting Positions (see figure 2)
Direct acting; see Handwheel Rotation	■ Standard mounting is with the input shaft perpendicular to the Hytork piston travel, with the handwheel opposite the actuator supply connections; ■ Optional mounting is with the handwheel on the same side as the Hytork actuator supply connections.
Manual Actuator Sizes	Approximate Weight without Handwheel
See tables 2, 3, and 4	Size AAA: 7.3 kg (16 lb) Size AA: 10 kg (22 lb) Size A: 14 kg (31 lb) Size B: 16 kg (35 lb) Size C: 24 kg (52 lb) Size D: 33 kg (72 lb)
Power Actuator Compatibility	Handwheel Weight
Compatible with all sizes of Hytork actuator; see tables 2, 3, and 4	6-inch: 1.0 kg (2.25 lb) 8-inch: 2.0 kg (4.50 lb) 12-inch: 4.0 kg (8.75 lb) 24-inch: 5.4 kg (12.00 lb) 30-inch: 6.7 kg (14.75 lb) 36-inch: 7.8 kg (17.25 lb)
Maximum Torque Output	
See tables 2, 3, and 4	
Wheel-Rim Force	
See tables 2, 3, and 4	
Handwheel Rotation	
Clockwise handwheel rotation closes valve (produces clockwise valve shaft rotation; as viewed from the actuator end of the shaft)	

Description

The 1079 manual actuator, shown in figure 1, is a declutchable unit for manual operation of keyed or square shaft control valves and equipment that use a Hytork actuator. The 1079 manual actuator mounts directly on the Hytork actuator and can be engaged to allow manual operation of the valve when the power actuator is not in use or disengaged to allow automatic operation of the valve by the power actuator. The mechanism used allows manual actuator engagement at any point of power actuator rotation.

Specifications

The 1079 manual actuator specifications are given in table 1.

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations.

To avoid personal injury or property damage resulting from the sudden release of pressure, do not install the valve assembly where service conditions could exceed the limits given on the valve and actuator nameplates. Use pressure-relieving devices as required by accepted industry, local, state, or Federal codes, and good engineering practices.

Check with your process or safety engineer for any other hazards that may be present from exposure to process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

The 1079 manual actuator is normally shipped mounted on the Hytork actuator. If the manual actuator is shipped separately for installation on the Hytork actuator, or if the manual actuator was removed for maintenance, mount the manual actuator by following the instructions in this section.

Field conversion of the Hytork actuator for use with the 1079 manual actuator requires fastening a mounting plate, included with the manual actuator, to the Hytork actuator. The 1079 actuator is installed between the valve and the Hytork actuator. Figure 2 shows the manual actuator standard and optional mounting positions. Typically the manual actuator is mounted with the input shaft perpendicular to the power actuator piston travel. However, the manual actuator can be mounted in any of four positions, provided there is sufficient clearance between the handwheel and the power actuator end caps. Fasten the mounting plate to the power actuator with the four mounting bolts provided with the manual actuator. Do not exceed the torque values given in table 5.

Figure 2. Fisher 1079 Actuator Mounting Positions

AG186

Installing the Manual Actuator

⚠ WARNING

Refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

NOTICE

Undertravel or overtravel of the valve disk, especially at the closed position, may result in poor valve performance and/or damage to the equipment. Make certain that the power actuator travel stops are properly set before installing and adjusting the manual actuator. Refer to the instruction manuals for the valve and the power actuator for information about setting travel stops.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Also shut off all pressure lines to the power actuator and release all pressure from the power actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. Make certain that the power actuator travel stops have been properly set.
3. For spring-return power actuators, allow the power actuator to remain in the position where the spring is relaxed. For double-acting power actuators, apply supply pressure as appropriate to position the valve disk in either the open or closed position.
4. Note whether the valve disk is in the open or closed position.
5. Engage the handwheel on the manual actuator. See the Engaging and Disengaging the Manual Actuator section in this manual for instructions. Perform one or the other of the following procedures.
 - If the valve disk is in the closed position: Rotate the handwheel clockwise until it stops.
 - If the valve disk is in the open position: Rotate the handwheel counterclockwise until it stops.
6. Disengage the manual actuator.
7. Slide the manual actuator shaft into the power actuator.
8. Rotate either the manual actuator or the power actuator slightly so that the mounting holes on the manual actuator align with the mounting holes in the mounting plate on the power actuator.
9. Fasten the manual actuator to the power actuator with the bolts, lockwashers, and nuts provided.
10. Install the power actuator and manual actuator assembly on the valve as described in the installation section of the power actuator instruction manual.

Operation

After the actuator and control valve assembly are installed, the manual actuator is ready for operation.

NOTICE

Applying too much torque to the actuator and valve parts could cause damage to the parts. To avoid such damage, do not exceed the maximum allowable torques listed in table 2, 3, or 4 or any other torque limitation of internal valve parts. Also, do not use wrenches or other devices on the handwheel or handwheel shaft to increase operating force.

If the force required to rotate the handwheel exceeds the wheel-rim force listed in table 2, 3, or 4, refer to the maintenance procedures.

Engaging and Disengaging the Manual Actuator

⚠ WARNING

Refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

Engaging the Manual Actuator

1. Shut off supply pressure to the power actuator.
2. Pull the ring on the detent mechanism to unlock the lever. Move the lever into the engaged position until it is against the stop pin and locked in position by the detent mechanism.
3. If applicable, open the power actuator bypass valve.

Disengaging the Manual Actuator

NOTICE

Disengaging the manual actuator when forces such as spring compression, cylinder pressure, and dynamic torque are present may cause sudden, extreme movement of all control valve components. This can result in damage to equipment and violent disturbance of the process. Before disengaging the manual actuator, approximate system balance should be achieved. Take appropriate steps to ensure that the return to automatic operation will not result in a extreme repositioning of control valve components.

1. Before disengaging the manual actuator, approximate system balance should be achieved. The system is in balance when the actual valve disk position is approximately the same as the position requested by the automatic control system. Under balanced system conditions, the manual actuator disengaging lever moves freely without use of excessive force. If after releasing the detent mechanism, the lever does not move freely toward the disengaged position, some system force is causing an imbalance. A forced return to automatic operation under these conditions can cause serious damage to the equipment and violent disturbance of the process.

2. If possible, determine whether the automatic control system is tending to open or close the valve disk, and rotate the handwheel in the appropriate direction until friction in the manual operator is reduced and the lever can be easily moved by hand. As an alternate approach, local manipulation of the supply pressure to the power actuator may bring the set point of the automatic system closer to the actual valve disk position.
3. If a smooth transition from manual to automatic operation cannot be ensured, isolate the valve from the process. Position the manual actuator so that it matches the position of the disk when no supply pressure is applied to the power actuator.
4. Pull the ring on the detent mechanism to unlock the lever. Push the lever into the disengaged position until it is against the stop pin and locked in position by the detent mechanism.
5. Close the bypass valve and return supply pressure to the power actuator.

Maintenance

WARNING

Avoid personal injury from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the power actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If the force required to rotate the handwheel exceeds the wheel-rim force listed in table 2, 3, or 4, check for the following conditions:

- Insufficient lubrication
- Seized actuator parts
- Excessive pressure drop across the valve, or
- Obstruction to the valve disk rotation.

If the manual actuator does not seem to control the process fluid, the worm or drive sleeve gear teeth may be broken, the handwheel pin may be sheared, or the internal power actuator or valve parts may be broken. Purchase a replacement manual actuator if necessary. Refer to the power actuator and valve instruction manuals if power actuator or valve maintenance is needed.

70 130 185 280	0.625-18 UNC	11	8
425A 680A	0.375-16 UNC	20	15
1125 1370	0.5-13 UNC	42	31
2585 4580	0.75-10 UNC	100	74

1. Applies to both double-acting and spring-return models.

Lubrication

The interior parts of the 1079 manual actuator should be lubricated on a regular schedule with a quality gear lubricant. The interior parts should also be lubricated whenever difficulty in handwheel rotation indicates a need for lubrication.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. Remove the bolts that secure the power actuator to the manual actuator, and remove the power actuator.
3. Remove the four cap screws that secure the gearbox cover plate and remove the gearbox cover plate.
4. Coat the worm, the drive sleeve gear teeth, and the bearing surfaces of the gearbox housing and worm with a quality gear lubricant.
5. Install the cover plate and four cap screws.
6. Install the power actuator on the manual actuator.

Figure 3. Fisher 1079 Declutchable Manual Actuator

Parts Ordering

When corresponding with your [Emerson sales office](#), indicate the size of the Hytork actuator. If the manual actuator was shipped separately (not attached to a Hytork actuator), give the serial number of the unit, which is shown on a tag attached to the manual actuator.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts List

Note

Contact your [Emerson sales office](#) for Part Ordering information.

Introduction

Scope of Manual

This instruction manual includes installation, operation, and maintenance information for the Fisher 1080 Declutchable Manual Actuator. Refer to separate instruction manuals for instructions covering the FieldQ actuator and the control valve.

Do not install, operate, or maintain a 1080 manual actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#).

Description

The 1080 manual actuator, shown in figure 1, is a declutchable unit for manual operation of Fisher control valves that use a FieldQ power actuator. The 1080 manual actuator mounts directly on the FieldQ actuator. It can be engaged to allow manual operation of the valve when the power actuator is not in use or disengaged to allow automatic operation of the valve by the power actuator. The mechanism used allows manual actuator engagement at any point of power actuator rotation.

Specifications

The 1080 manual actuator specifications are given in table 1.

1080 Manual Actuator

May 2023

Figure 2. Fisher 1080 Actuator Mounting Positions

NOTE:
RIGHT AND LEFT HAND MOUNTING IS BASED ON THE 8580 VALVE DRIVE SHAFT BEING MOUNTED IN THE RECOMMENDED HORIZONTAL POSITION.

7580768
B2702

Installation

The 1080 manual actuator is normally shipped mounted between the valve assembly and the FieldQ actuator. If the manual actuator is shipped separately for installation on the FieldQ actuator, or if the manual actuator was removed for maintenance, mount the manual actuator by following the instructions in this section.

Field conversion of the FieldQ actuator for use with the 1080 manual actuator requires fastening an adaptor plate, included with the manual actuator, to the FieldQ actuator. The 1080 actuator is installed between the valve and the FieldQ actuator.

Figure 2 shows the manual actuator mounting positions. Positions 1 and 3 are possible with all sizes of the FieldQ. Positions 2 and 4 are only possible for FieldQ sizes Q40 through Q350 and Q1600. Fasten the adaptor plate to the power actuator with the mounting bolts provided with the manual actuator. Use the torque values given in table 3.

Installing the Manual Actuator

If you purchased the 1080 actuator as part of a valve and power actuator assembly, step 13 is the only step you will need to perform in the following procedures. If you purchased the 1080 actuator separately, perform all the steps and read all warnings and cautions below.

⚠ WARNING

Refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Also shut off all pressure lines to the power actuator and release all pressure from the power actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. For spring-return power actuators, allow the power actuator to remain in the position where the spring is relaxed. For double-acting power actuators, apply supply pressure as appropriate to position the valve disk in either the open or closed position.
3. Note whether the valve disk is in the open or closed position.
4. Engage the handwheel on the manual actuator. See the Engaging and Disengaging the Manual Actuator section in this manual for instructions.
5. If using position 1 or 3 from figure 2, rotate the handwheel to line up the index mark on the top of the manual actuator shaft and the drive shaft on the top of the power actuator. If using position 2 or 4 from figure 2, the index mark on top of the power actuator input drive on the 1080 must be perpendicular to the face of the valve disk and the slot in the top of the power actuator shaft (see figure 3).
6. Determine the correct relative positions of the power and manual actuators (see figure 2).
7. Remove the adaptor plate on the top of the gear box (see figure 3).
8. Attach the adaptor plate to the bottom of the power actuator with bolts furnished with the adaptor plate.
9. Slide the power actuator input drive into the power actuator (see figure 3).
10. Rotate either the manual actuator or the power actuator slightly so that the mounting holes on the manual actuator align with the mounting holes in the mounting plate on the power actuator.
11. Fasten the manual actuator to the mounting plate with the bolts, washers and nuts provided (see table 3).
12. Install the power actuator and manual actuator assembly on the valve as described in the installation section of the power actuator instruction manual. Remember the positions noted in steps 3 and 6, because you will need them when aligning the drive shaft on the top of the power actuator and the valve shaft.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

Instruction Manual

D500236X012

1080 Manual Actuator

May 2023

NOTICE

Undertravel or overtravel of the valve disk, especially at the closed position, may result in poor valve performance and/or damage to the equipment. Make certain that the power actuator travel stops are properly set before installing the valve. Refer to the instruction manuals for the power actuator for information about setting travel stops.

13. Make certain that the power actuator travel stops have been properly set. FieldQ actuator travel stops, the travel stop adjustments are made in the power actuator. The adjusting travel stops procedure is in the FieldQ [Instruction Manual](#).
14. Install the valve in the line using the instructions in the valve instruction manual.

Operation

After the actuator and control valve assembly are installed, the manual actuator is ready for operation.

⚠ WARNING

Applying too much torque to the actuator and valve parts could cause damage to the parts and result in loss of control of key internal valve components (e.g. disk or ball). This loss of control may result in personal injury due to a sudden increase or decrease of pressure within -- or release of pressure from -- the pipeline. To avoid such damage or personal injury, do not exceed the wheel rim force listed in table 2. Also, do not use wrenches or other devices on the handwheel or handwheel shaft to increase operating force.

If the force required to rotate the handwheel exceeds the wheel-rim force listed in table 2, refer to the Maintenance procedures.

¹. Only the 1080/FieldQ combinations shown are available.
². Maximum torque output of the 1080 actuator only.
³. Torque output of the FieldQ actuator at 100 psig and required 1080 torque output for use with the FieldQ.
⁴. Amount of force necessary at rim of the handwheel to match torque output of the FieldQ at 100 psig.

Engaging and Disengaging the Manual Actuator

Engaging the Manual Actuator

1. Engage the manual actuator **before** venting the power actuator loading pressure. Releasing the air pressure prior to engaging could result in undesirable valve rotation.

⚠ WARNING

Undesirable valve rotation or loss of control of key internal valve components (e.g. disk/ball), may result in personal injury due to a sudden increase or decrease of pressure within - or release of pressure from - the pipeline.

2. Pull the ring on the detent mechanism to unlock the lever. At the same time, move the lever into the engaged position until it is against the stop pin and locked in position by the detent mechanism. See figure 3.
3. If the lever sticks midway, turn the handwheel 1/3 turn (2 full turns for units with additional gearbox between the handwheel and lever). Then try the detent lever again. Repeat this step as necessary, turning the handwheel in the same direction, until the lever moves freely (see figure 4). The reason the lever may stick is that the worm is not in proper alignment with the gear (see figure 4). Rotation of the worm will allow for proper alignment. Excessive force should not be required.
4. Shut off supply pressure to the power actuator and bleed off or equalize pressure in the cylinders. If applicable, open the power actuator bypass valve.

Note

If the loading pressure in the power actuator has already been released, you will not need to use the optional bypass relief valve.

Disengaging the Manual Actuator

⚠ WARNING

Disengaging the manual actuator when forces, such as spring compression, cylinder pressure, and dynamic torque, are present may cause sudden, extreme movement of all control valve components. Disengaging the lever with excessive force can result in damage to equipment and violent disturbance of the process.

Damage to equipment resulting in loss of control of internal valve components (e.g. disk/ball) - or violent disturbance of the process may result in personal injury due to a sudden increase or decrease of pressure within - or release of pressure from - the pipeline.

Before disengaging the manual actuator, take appropriate steps to ensure that the return to automatic operation will not result in an extreme repositioning of control valve components. Procedures to determine approximate system balance are given in the following steps.

1. Approximate system balance should be achieved, before disengaging the manual actuator. The system is in balance when the actual valve disk position is approximately the same as the position requested by the automatic control system. Under balanced system conditions, the manual actuator disengaging lever moves freely without use of excessive force.

If after releasing the detent mechanism, the lever does not move freely toward the disengaged position, some system force is causing an imbalance. A forced return to automatic operation under these conditions can cause serious damage to the equipment and violent disturbance of the process.

2. If possible, determine whether the automatic control system is tending to open or close the valve disk, and rotate the handwheel in the appropriate direction until the lever can be easily moved by hand. As an alternate approach, local manipulation of the supply pressure to the power actuator may bring the set point of the automatic system closer to the actual valve disk position.
3. If a smooth transition from manual to automatic operation cannot be ensured, isolate the valve from the process. On Spring Return actuators, position the manual actuator and the disk to the spring fail open or close (whichever is applicable) end of travel so that no position changes will happen when supply pressure is applied to the power actuator. On double-acting actuators, this positioning will not be necessary.
4. Pull the ring on the detent mechanism to unlock the lever. Push the lever into the disengaged position until it is against the stop pin and locked in position by the detent mechanism.
5. Close the bypass valve, if needed, and return supply pressure to the power actuator.

Maintenance

⚠ WARNING

Avoid personal injury from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the power actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression. If using a Spring Return actuator, first check to make sure the valve has been moved to the fail safe position to prevent unexpected actuator movement.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If the force required to rotate the handwheel exceeds the wheel-rim force listed in table 2 check for the following conditions:

- Insufficient lubrication
- Seized actuator parts
- Excessive pressure drop across the valve, or
- Obstruction to the valve disk rotation.

If the manual actuator does not seem to control the process fluid, the worm or drive sleeve gear teeth may be broken, the handwheel pin may be sheared, or the power actuator or internal valve parts may be broken.

Refer to the power actuator and valve instruction manuals if power actuator or valve maintenance is needed.

Lubrication

The interior parts of the 1080 manual actuator should be lubricated on a regular schedule with a quality gear lubricant. The interior parts should also be lubricated whenever difficulty in handwheel rotation indicates a need for lubrication.

⚠ WARNING

Before performing any of these lubrication procedures, observe the steps in the WARNING at the beginning of the Maintenance section.

1. Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. If using a power actuator, also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
2. Remove the bolts that secure the power actuator to the manual actuator adaptor plate and remove the power actuator.
3. Remove the cap screws that secure the gearbox lid and remove the gearbox lid.
4. Coat the worm, the drive sleeve gear teeth, and the bearing surfaces of the gearbox housing and worm with a quality gear lubricant.
5. Replace the cover plate and cap screws using the bolt torques listed in table 5.
6. Replace the power actuator on the manual actuator. Fasten the manual actuator to the adaptor plate using the torque values in table 3.

Section 1: Introduction

1.1 Scope of the Manual

This instruction manual includes installation, adjustment, operation, maintenance and parts information for the Fisher 2052 diaphragm rotary actuator (Figure 1). Instructions for the control valve, positioner, manual actuator and other accessories are included in separate manuals.

WARNING

Do not install, operate or maintain a 2052 actuator without being fully trained and qualified in valve, actuator and accessory installation, operation and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your Emerson sales office before proceeding.

1.2 Description

2052 spring-and-diaphragm rotary actuators are used on rotary-shaft valve bodies for throttling or on-off applications. The 2052 may be used for on-off service without a positioner or it may be used for throttling service with a positioner, depending on service conditions. The 2052 has an ISO 5211 mating interface that allows installation to non-Fisher valves. Refer to separate bulletins for valve and positioner information.

A top-mounted handwheel option is available for infrequent service as a manual actuator. For repeated or daily manual operation, the unit should be equipped with a side-mounted declutchable 1078 manual actuator. Externally adjustable travel stops are used to limit the degree of rotation at both ends of the actuator stroke.

The lever for the 2052 actuator is supported by bushings. The lever may be changed to accommodate valve bodies with different size valve shafts.

Optional stainless steel lever available for use in corrosive environments. Standard ductile iron levers required for use with 1078 Declutchable Manual Operator, lockout and ISO 5211 square insert.

2052 levers are available with or without a quad square feature, see Figure 3. This feature is needed for options like 1078 side-mounted handwheels, lockout devices on sizes 2 and 3 and square shaft insert for ISO 5211 mounting. Verify whether this feature is present on the existing lever prior to ordering parts to add one of these options. A replacement lever may need to be ordered as well. See Section 3.3 on how to replace the lever.

Actuator Temperature Capabilities ⁽¹⁾	Standard: -45 to 80°C / -50 to 176°F Optional: -45 to 100°C / -50 to 212°F ⁽³⁾ or -60 to 80°C / -76 to 176°F ⁽⁴⁾
Operation	Field reversible between PDTC and PDT0; right- and left-hand mounting, any angle of orientation
Approximate Weight	Size 1: 22.2 kg / 49 lb Size 2: 54.4 kg / 120 lb Size 3: 113 kg / 250 lb
Controller/Positioners Available	DVC2000, DVC6020, DVC6030, DVC6200, 3610J, 3620J, 4190, C1
Adjustable Travel Stops	Standard adjustable up and down stops capable of 30 degrees of adjustment per stop.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

Instruction Manual

D103296X012

2052 Actuator

September 2025

Table 1. Fisher 2052 Actuator Specifications (continued)

Specifications	
Accessories Available	846, 646, 2625 and 67C Series, switches, i2P-100, VBL, DXP, GO Switch™
Handwheel	Top-mounted handwheel: Optional on Sizes 1, 2 and 3 actuators Declutchable handwheel: Optional on Sizes 1, 2 and 3 actuators
Operational Lockout ⁽²⁾	Available for customer-supplied padlock to lock the actuator in the spring-fail position
1. The pressure/temperature limits in this manual should not be exceeded. The current SIL certification for the 2052 actuator is only relevant for the standard temperature ratings shown. 2. Lockout and declutchable handwheel cannot be used together on sizes 2 and 3 actuators. 3. Temperature range only applies when using silicone diaphragm material. Silicone diaphragm is not available with the top-mounted handwheel option. 4. Temperature range requires use of stainless steel bolting for yoke and travel stops. Not available with top-mounted handwheel.	

Table 2. Actuator and Lever Availability for Shaft Sizes

SHAFT SIZE		DUCTILE IRON LEVER			STAINLESS STEEL LEVER		
		Actuator Size					
mm	in.	1	2	3	1	2	3

1.4 Specifications

Specifications are shown in Table 1 for 2052 actuators. Specifications for actuator operation are stamped on a metal nameplate attached to the actuator.

Table 6. Bolting Torque Requirements^(1, 2)

DESCRIPTION KEY NUMBER	ACTUATOR SIZE	TORQUE		FASTENER LUBRICATION
		N•m	Lbf•ft	
Rod End Bearing Clamping Bolt Torque, Key 16	1	38	28	Threadlocker
	2	180	130	
	3	400	295	
End Plate to Housing Bolt Torque, Key 4	1	68	50	None
	2	120	90	
	3	210	155	
Diaphragm Plate to Rod Bolt Torque, Key 7	1	27	20	Anti-Seize Lubricant
	2	115	85	
	3	300	220	
Casing Bolt Torque, Key 8	1	55	40	None
	2	55	40	
	3	55	40	
Housing to Yoke Bolt Torque, Key 28	1	27	20	None
	2	68	50	
	3	245	180	
Lever-Spline Clamping Bolt Torque, Key 15	1	38	28	None
	2	115	85	
	3	175	130	
Optional Lockout Kit Mounting Bolt Torque, Key 53	1	N/A	N/A	None
	2	88	65	
	3	340	250	

1. Exceeding any torque requirements could damage the actuator and impair safe operation.

2. For other lubricants, contact your [Emerson sales office](#) for torques.

Section 2: Installation

WARNING

Always wear protective gloves, clothing and eyewear when performing any installation operations.

Check with your process or safety engineer for any other hazards that may be present from exposure to process media.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

WARNING

To avoid personal injury and parts damage, do not apply pressure that exceeds the Maximum Diaphragm Casing Pressure in Table 1. Use pressure-limiting or pressure-relieving devices to prevent the Operating Pressure from exceeding the values shown in Table 3.

The actuator, as it comes from the factory, is normally mounted on a valve body. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the procedures presented in the Actuator Mounting section. Follow the procedures given in the valve instruction manual when installing the control valve in the pipeline.

If a positioner is ordered with the actuator, the pressure connection to the actuator is normally made at the factory. If it is necessary to make this connection, run tubing of the appropriate size for the diaphragm casing pressure connection (reference Table 5) between the pressure connection and the instrument. Keep the length of tubing or pipe as short as possible to avoid transmission lag in the control signal.

When the control valve is completely installed and connected to the controlling instrument, check to make sure that the action is correct (air-to-open or air-to-close) and that the controlling instrument is properly configured for the desired action. For successful operation, the diaphragm rod assembly, lever and valve shaft must move freely in response to changes in the loading pressure on the diaphragm.

2.1 Actuator Mounting

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- **Do not remove the actuator from the valve while the valve is still pressurized.**
- **Always wear protective gloves, clothing and eyewear when performing any maintenance operations.**
- **Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.**
- **Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.**
- **Safely vent the power actuator loading pressure.**
- **Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.**
- **The valve packing box may contain process fluids that are pressurized, even when the valve has been removed from the pipeline. Process fluids may spray out under pressure when removing the packing hardware or packing rings.**
- **Check with your process or safety engineer for any hazards that may be present from exposure to process media.**

Use the following steps to mount the actuator or to change actuator mounting style or position.

Unless otherwise specified, key numbers referenced in the following procedures are shown in Figure 8 for the 2052 actuator.

If the actuator is mounted on a valve body and it is necessary to change mounting style or position, the actuator must first be separated from the valve body.

1. Isolate the valve body from the process. Release process pressure and vent all actuator pressure.
2. Remove the cover or plug (key 2).

WARNING

To avoid personal injury and equipment damage from moving parts, keep fingers and tools clear while stroking the actuator with the cover removed.

3. Loosen the cap screw (key 15).

4. Separate the actuator from the valve body by removing the cap screws and nuts which secure the valve to the mounting yoke (key 27). Proceed to step 5.

If the actuator is not mounted on a valve body, ensure the up and down travel stops (see Figure 4) are adjusted correctly to achieve the desired actuator rotation. Use the travel indicator (key 21) and travel scale (key 19) as reference.

NOTE

Once each travel stop is properly positioned, adequately tighten the hex nut (key 24) to lock the travel stop in place.

5. Refer to Figure 2 and Table 4 for available mounting styles and positions. The actuator is normally positioned vertically with the valve in a horizontal pipeline.
6. Determine whether the actuator mounting yoke (key 27) will be mounted on the end plate assembly (key 3) side or on the actuator housing boss side of the actuator. If the desired mounting position and style require moving the mounting yoke (key 27) and travel indicator components to opposite sides of the actuator, remove the machine screws (keys 20 and 22), the travel indicator scale (key 19) and the travel indicator (key 21). Remove the cap screws (key 28) and the mounting yoke (key 27). Install the mounting yoke in the desired position (on the end plate assembly or on the actuator housing boss). Tighten the mounting cap screws to the torque specified in Table 6. Install the travel indicator components on the opposite side of the actuator.

⚠ WARNING

To avoid personal injury or property damage, ensure the travel indicator is installed correctly to coincide with the desired actuator action. Refer to Figure 4 for more information.

Figure 4. Fisher 2052 Actuator Travel Stops and Travel Indication

7. Before sliding the valve shaft into the lever, position the valve ball or disk as follows:
For push-down-to-close action, the valve ball or disk should be in the fully open position.
For push-down-to-open action, the valve ball or disk should be in the fully closed position (see the valve body instruction manual).
8. Make sure that the index markings on the valve shaft are properly aligned with either the markings on the lever or the travel indicator scale mounting holes. Slide the valve shaft into the lever. (See Figure 5 for one possible orientation.) Install the valve mounting cap screws and nuts. Tighten to the torque value given in the appropriate valve body instruction manual.
9. Ensure all end play in the valve shaft is removed by directing the valve shaft and control element toward the actuator as much as possible.
10. Tighten the socket head cap screw (key 15) which compresses the splined lever connection to the valve shaft (see Table 6). Install the cover or plug (key 2) into the access hole in the housing.

NOTICE

When adjusting the travel stop for the closed position of the valve ball or disk, refer to the appropriate valve instruction manual for detailed procedures. Undertravel or overtravel at the closed position may result in poor valve performance and/or damage to the equipment.

Over-rotation of the lever could result in the diaphragm stroking to the point where the diaphragm seals off against the air signal connection. This could prevent an air signal from being able to stroke the valve.

11. Adjust the up travel stop (see Figure 4) so that the valve ball or disk is in the desired position. When adjusting the up travel stop, ensure the stop is not backed out too far, causing the lever to over-rotate. Over-rotation of the lever may cause damage to valve components. Avoid over-rotation by adjusting the up travel stop so that the travel indicator screws (key 22) align with the travel scale screws (key 20). See Figure 4.
12. Stroke the actuator and adjust the down travel stop so that the valve ball or disk is in the desired position.

NOTE

Once each travel stop is properly positioned, adequately tighten the hex nut (key 24) to lock the travel stop in place.

13. Make sure that the travel indicator pointer matches the ball or disk position. Remove and install in the proper position if necessary.
14. Refer to the table of contents for accessory installation procedures.

Section 3: Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of service conditions. Instructions are given below for disassembly and assembly of parts. Key numbers referenced in the following steps are shown in Figure 8 for the 2052, except as listed below or otherwise specified in the procedures.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- **Do not remove the actuator from the valve while the valve is still pressurized.**
- **Always wear protective gloves, clothing and eyewear when performing any maintenance operations.**
- **Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.**
- **Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.**
- **Safely vent the power actuator loading pressure.**
- **Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.**
- **Check with your process or safety engineer for any hazards that may be present from exposure to process media.**

3.1 Replacing Diaphragm

Isolate the valve body from the process. Release process pressure and vent all actuator pressure.

Disassembly

1. Remove the supply tubing or pipe from the top casing assembly (key 5).

WARNING

To avoid personal injury from precompressed spring force suddenly thrusting parts away from the actuator, spring compression must first be relieved. Closely follow the instructions below.

Figure 5. Orientation of the Fisher 2052 Actuator Lever into the Housing and Aligning the Actuator to the Valve Shaft Markings

2. Loosen, but do not remove, all casing cap screws and hex nuts (keys 8 and 9). Ensure there is no spring force to the top casing assembly (key 5). If spring force is detected against the top casing assembly, ensure the up travel stop cap screw (key 23) is adjusted correctly to prevent over-rotation of the lever (key 14). Refer to Figure 4. The travel indicator screws (key 22) in the end of the lever should be in alignment with the travel scale screws (key 20). If the up travel stop is confirmed to be adjusted correctly and force is still detected against the top casing assembly, contact your local Emerson service center. Alternatively, replace two oppositely located casing cap screws (key 8) with 100 mm / 4 in. long fully threaded M10 cap screws of ISO 898-1 Property Class 8.8 material or equivalent. Loosen the nuts (key 9) on the two fasteners in an equivalent manner to relieve spring force.
3. Carefully remove all cap screws and hex nuts (keys 8 and 9) from the top casing assembly. The spring forces are retained by the diaphragm rod assembly (key 10), allowing quick removal of the pressure retaining components.
4. Remove the top casing assembly and the diaphragm (key 11).
5. Inspect the diaphragm plate (key 6). If the diaphragm plate is damaged or if further disassembly of the actuator is required, proceed to the Replacing Diaphragm Plate, Diaphragm Rod Assembly and Spring(s) procedure.
6. Inspect the diaphragm and replace if necessary.

Assembly

1. Place the diaphragm (key 11) on the diaphragm plate (key 6), making certain that it is properly centered.
2. Observe the correct position of the loading connection fitting and install the top casing assembly (key 5). Replace the cap screws and nuts (keys 8 and 9) which secure the top casing assembly to the actuator housing. Tighten the nuts in an alternating fashion (see Table 6).
3. Install the inlet piping to the top casing assembly.

3.2 Replacing Diaphragm Plate, Diaphragm Rod Assembly and Spring(s)

Isolate the valve body from the process. Release process pressure and vent all actuator pressure.

Disassembly

1. Remove the supply tubing or pipe from the top casing assembly (key 5).

WARNING

To avoid personal injury from precompressed spring force suddenly thrusting parts away from the actuator, spring compression must first be relieved. Closely follow the instructions below.

2. Loosen, but do not remove, all casing cap screws and hex nuts (keys 8 and 9). Ensure there is no spring force to the top casing assembly (key 5). If spring force is detected against the top casing assembly, ensure the up travel stop cap screw (key 23) is adjusted correctly to prevent over-rotation of the lever (key 14). Refer to Figure 4. The travel indicator screws (key 22) in the end of the lever should be in alignment with the travel scale screws (key 20). If the up travel stop is confirmed to be adjusted correctly and force is still detected against the top casing assembly, contact your local Emerson service center. Alternatively, replace two oppositely located casing cap screws (key 8) with 100 mm / 4 in. long fully threaded M10 cap screws of ISO 898-1 Property Class 8.8 material or equivalent. Loosen the nuts (key 9) on the two fasteners in an equivalent manner to relieve spring force.
3. Carefully remove all cap screws and hex nuts (keys 8 and 9) from the top casing assembly. The spring forces are retained by the diaphragm rod assembly (key 10), allowing quick removal of the pressure retaining components.
4. Remove the top casing assembly and the diaphragm (key 11).

5. Inspect the diaphragm plate (key 6).
 - a. To relieve spring compression, using a hex wrench, unscrew and remove the socket head cap screw (key 7) which secures the diaphragm plate (key 6) to the diaphragm rod assembly (key 10). Remove the diaphragm plate.
6. Remove the spring (key 13) or springs (keys 12 and 13).
7. The guide assembly (key 48) may be removed for inspection (size 3 only).

NOTE

At this stage of disassembly, it may be determined that further disassembly is not necessary. If separation of the diaphragm rod assembly from the lever is not warranted, proceed to the Assembly portion within this section of the procedure.

8. To gain access to the cap screw (key 16) which secures the diaphragm rod assembly to the lever, the end plate assembly (key 3) must be removed. Before the end plate assembly can be removed, one of the following procedures must be performed. Proceed as appropriate:
 - For actuators with valve bodies mounted on the end plate assembly (key 3) side of the actuator, the actuator must be separated from the valve body. Perform steps 1 through 4 of the Actuator Mounting section, remove the mounting yoke (key 27) and then return to step 9 of this section.
 - For actuators with valve bodies mounted on the actuator housing boss side of the actuator [opposite of the endplate (key 3)], remove the travel indicator pointer (key 21). Proceed to step 9.
9. Remove the socket head cap screws (key 4) and the end plate assembly (key 3).
10. Remove the cap screw (key 16) and nut (key 17) if applicable (size 3 only), that secures the actuator lever (key 14) to the diaphragm rod assembly (key 10). Remove the diaphragm rod assembly.
11. Inspect all parts and replace if necessary.
12. If total disassembly of the actuator is required or if the actuator will be assembled for use with a valve body with a different valve shaft diameter, proceed to the Changing or Replacing Actuator Lever procedure.

Assembly

1. Fasten the diaphragm rod assembly (key 10) to the lever using the cap screw (key 16) and nut (key 17) if applicable. Tighten per Table 6.
2. Install the housing end plate (key 3).
3. Adjust the travel stop bolts to the correct position so that the travel indicator screws (key 22) align with the travel scale screws (key 20). See Figure 4.
4. Install the guide assembly (key 48 - size 3 only).
5. Install the spring(s). The outer (larger diameter) spring is standard for the single spring sizes 1 and 2 constructions. The inner spring is standard for the single spring size 3 construction.
6. Place the diaphragm plate (key 6) onto the spring(s). It is important that the springs be properly seated in their respective counterbores on the bottom side of the plate. If necessary, push or pull the diaphragm plate toward center to ensure the springs are engaged into their respective seats.
7. Lubricate the socket head capscrew (key 7) and tighten per Table 6.
8. Place the diaphragm (key 11) on the diaphragm plate (key 6), making certain that it is properly centered.
9. Observe the correct position of the loading connection fitting and install the top casing assembly (key 5). Replace the cap screws and nuts (keys 8 and 9) which secure the top casing assembly to the actuator housing. Tighten the nuts in an alternating fashion (see Table 6).
10. Install the inlet piping to the top casing assembly.
11. Install the travel indicator (key 19) if removed.
12. If the actuator was removed from the valve body, refer to the appropriate section in the Actuator Mounting procedure and proceed as applicable.

3.3 Changing or Replacing Actuator Lever

WARNING

Avoid personal injury or property damage. The end plate assembly (key 3) and lever (key 14) may only be removed after the actuator spring compression forces are safely relieved. Refer to the instructions below.

Disassembly

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- **Do not remove the actuator from the valve while the valve is still pressurized.**
- **Always wear protective gloves, clothing and eyewear when performing any maintenance operations.**
- **Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.**
- **Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.**
- **Safely vent the power actuator loading pressure.**
- **Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.**
- **Check with your process or safety engineer for any other hazards that may be present from exposure to process media.**

1. Isolate the valve body from the process. Release process pressure and vent all actuator pressure.
2. Remove the cover or plug (key 2).

WARNING

To avoid personal injury and equipment damage from moving parts, keep fingers and tools clear while stroking the actuator with the cover removed.

3. Loosen the cap screw (key 15).
4. Follow steps 2 through 10 in the Replacing Diaphragm Plate, Diaphragm Rod Assembly and Spring(s) section.
5. Remove and inspect the lever (key 14). If the lever is worn or damaged or if the actuator will be mounted to a valve body requiring a different size lever, replace the lever.
6. Inspect the bushings located in the end plate (key 3) and housing (key 1) assemblies. If bushings are excessively worn or damaged, remove them with a press. Press in new bushings so that they are flush with the exterior surfaces of the actuator housing and the end plate assembly.

Assembly

1. Refer to Figure 5 for the correct orientation of the lever during assembly.
2. If a cam-operated positioner is used, install the cam to the lever with the parts provided by the appropriate instrument mounting kit. Be sure to observe the orientation shown in Figure 5 and follow all procedures given in the positioner instruction manual.
3. Insert the lever into the bushing in the actuator housing.
4. Fasten the rod end bearing diaphragm rod assembly to the lever using the cap screw (key 16) and nut (key 17) if applicable. Tighten per Table 6.
5. Install the end plate assembly (key 3).
6. Adjust the travel stop bolts to the correct position so that the travel indicator screws (key 22) align with the travel scale screws (key 20). See Figure 4.
7. Install the guide assembly (key 48) size 3 only.
8. Install the spring(s). The outer (larger diameter) spring is standard for the single spring sizes 1 and 2 constructions. The inner spring is standard for the single spring size 3 construction.
9. Place the diaphragm plate (key 6) onto the spring(s). It is important that the springs be properly seated in their respective counterbores on the bottom side of the plate. If necessary, push or pull the diaphragm plate toward center to ensure the springs are engaged into their respective seats.
10. Lubricate the socket head capscrew (key 7) and tighten per Table 6.
11. Place the diaphragm (key 11) on the diaphragm plate (key 6), making certain it is properly centered.
12. Observe the correct position of the loading connection fitting and install the top casing assembly (key 5). Replace the cap screws and nuts (keys 8 and 9) which secure the top casing assembly to the actuator housing. Tighten the nuts in an alternating fashion (see Table 6).
13. Install the inlet piping to the top casing assembly.
14. Refer to the Actuator Mounting procedure and proceed as applicable.

3.4 Positioner Mounting (3610, DVC6020 or DVC6200)

1. Before installing the positioner, the positioner cam must be installed on the lever.
2. Refer to assembly step 2 in the previous section on Changing or Replacing Actuator Lever.
3. Refer to the positioner instruction manual for setup and calibration procedures.

3.5 Top-Mounted Handwheel (All Sizes)

Key numbers used in this procedure are shown in Figures 10 (Sizes 1 and 2) and 11 (Size 3) except where indicated.

The optional top-mounted handwheel can be used as a manual actuator for intermittent service. It is not to be used as an adjustable travel stop. This is built into the housing.

The handwheel assembly is welded to a special top casing assembly (key 5, Figures 10 and 11). A hex nut (key 43) locks the handwheel in position. For field installation of a handwheel, the special upper diaphragm casing is supplied with the handwheel.

Turning the handwheel (key 32) clockwise into the upper casing forces the pusher plate (key 36) against the diaphragm and diaphragm plate (keys 11 and 6, Figure 8) to compress the inner and outer springs (keys 12 and 13, Figure 8) and move the diaphragm rod assembly downward. Turning the handwheel counter-clockwise allows the actuator spring(s) to move the diaphragm rod assembly upward.

NOTICE

Damage to the handwheel screw can occur if the handwheel is over-rotated in the counter-clockwise direction. The handwheel should not continue to be rotated once the actuator reaches the up stop and resistance to turning the handwheel significantly drops.

Instructions are given below for complete disassembly and assembly required for inspection and parts replacement.

Disassembly

WARNING

To avoid personal injury from the precompressed spring force thrusting the upper diaphragm casing away from the actuator, fully turn the handwheel counterclockwise.

1. Perform steps 1 through 6 of the Replacing Diaphragm procedure.
2. Remove the cotter pin, hex nut, handwheel and locknut (keys 34, 33, 32 and 43). Unscrew the stem (key 35) out through the actuator end of the handwheel body (key 5). Size 3 also requires removal of spacer (key 42).
3. Check the condition of the O-ring (key 44); replace if necessary.
4. For Sizes 1 and 2, if it is necessary to remove the pusher plate or spacer (key 36 or 42), drive out the groove pin (key 37).
5. For the Size 3, remove cap screw (key 59) if the pusher plate or thrust bearing needs to be removed.

Assembly (Sizes 1 and 2)

1. Before assembling, lubricate the thread of the stem (key 35) with anti-seize lubricant. Lubricate the bearing surfaces of the stem and rounded end with lithium grease.
2. If the pusher plate or spacer was removed, attach them to the stem and drive in a new groove pin (key 37).
3. With the O-ring (key 44) in place, thread the stem into the handwheel assembly.
4. Install the locknut, handwheel, hex nut and cotter pin (keys 43, 32, 33 and 34).

NOTE

Be sure to install the handwheel so that the arrow of operation on the top side coincides with the action of the actuator, as stated on the nameplate. (The arrow should point clockwise for PDO. The arrow should point counter-clockwise for PDTCT).

5. Install the top casing assembly, making certain the warning tag is in place on the casing flange.

Assembly (Size 3)

1. Before assembling, lubricate the thread and bearing surfaces of the handwheel screw (key 35) with grease (key 60).
2. If the pusher plate was removed, lubricate thrust bearing (key 56) and thrust bearing races (key 55) with grease (key 60) and place inside top of pusher plate (key 36).
3. Insert the bottom of handwheel screw (key 35) through the pusher plate, thrust bearing, and thrust bearings races. Apply thread sealant (key 59) to screw (58) to capture the pusher plate onto the end of the handwheel screw.
4. Lubricate O-ring (key 44) with grease (key 60) and install into top casing assembly.
5. With the O-ring (key 44) in place, thread the stem into the handwheel assembly.
6. Install the locknut, handwheel, hex nut, spacer and cotter pin (keys 43, 32, 33, 42 and 34).

NOTE

Be sure to install the handwheel so that the arrow of operation on the top side coincides with the action of the actuator, as stated on the nameplate (The arrow should point clockwise for PDO. The arrow should point counter-clockwise for PDTCT).

7. Install the top casing assembly, making certain the warning tag is in place on the casing flange.

Section 4: Locking Mechanism

Refer to Figure 6 or 7 for the appropriate size locking mechanism when installing or planning to operate the device.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- **Do not remove the actuator from the valve while the valve is still pressurized.**
- **Always wear protective gloves, clothing and eyewear when performing any maintenance operations.**
- **Disconnect any operating lines providing air pressure, electric power or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.**
- **Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.**
- **Safely vent the power actuator loading pressure.**
- **Check with your process or safety engineer for any hazards that may be present from exposure to process media.**

4.1 Installing the Size 1 Locking Mechanism

To add the locking mechanism (Figure 6) to an existing actuator, purchase the required kit from Emerson.

1. Ensure the diaphragm rod assembly (key 10) is in the upward position and the lever (key 14) is against the up travel stop (spring fail position).
2. Thread the supplied jam nut (key 40) all the way onto the threaded bolt portion of the mounting plate assembly.
3. Loosen the down travel stop hex nut (key 24) and remove the travel stop cap screw (key 23).
4. Remove the vent screen (key 47) from the threaded hole in the bottom of the actuator housing.
5. Secure the locking plate (key 39) to the bottom of the housing assembly by reinstalling the down travel stop (key 23) and hex nut (key 24). Ensure the clearance hole in the locking plate is aligned with the threaded hole in the bottom of the housing.
6. Ensure the down travel stop is adjusted correctly to achieve the desired actuator rotational output.
7. Install the mounting plate assembly (key 38) by inserting it through the clearance hole in the locking plate and threading it into the hole in the actuator housing.

Figure 6. Size 1 Locking Mechanism

GE51941_A

Operating the Locking Mechanism (Size 1)

To Lock the Actuator

1. Screw the mounting plate assembly into the housing until it contacts the actuator lever.
2. Align the hole in the locking plate (key 39) with one of the holes in the disk of the mounting plate assembly.
3. Tighten the jam nut (key 40) against the locking plate.
4. Insert a padlock (not furnished by Emerson) to prevent the mounting plate assembly from rotating.

To Unlock the Actuator

1. Remove the padlock. Loosen the jam nut (key 40) and unscrew the threaded bolt until it no longer protrudes inside the housing.

NOTE

Ensure the mounting plate assembly bolt is unthreaded far enough that the actuator lever will not contact the bolt during normal actuator operation.

2. If the mounting plate assembly is to be left partially threaded into the housing, lock it with the jam nut (key 40) so that it cannot be screwed further into the housing and interfere with normal actuator operation.

Figure 7. Sizes 2 and 3 Locking Mechanism

4.2 Installing the Sizes 2 and 3 Locking Mechanism

To add the locking mechanism (Figure 7) to an existing actuator, purchase the required kit from Emerson. Verify the actuator lever has the quad square feature. The lever will need to be replaced to install a lockout on an actuator that has a lever without the quad square. See the section for "Changing or Replacing Actuator Lever".

1. The actuator should be mounted to the valve body and both travel stops (key 23) properly positioned prior to installing the locking mechanism.
2. Ensure the actuator lever (key 14) is in the spring-fail position (against the up travel stop).
3. Assemble the lockout kit by positioning the locking shaft (key 50) within the center through-hole of the mounting plate (key 51), as shown in Figure 7. Insert the locking pin (key 52) through the center pinhole of the mounting plate and through the pin hole in the locking shaft. Install the hairpin cotter pin (key 54) for retention.
4. If installing the lockout kit on an existing actuator, remove the travel indicator (key 21) and travel indicator scale (key 19) from the actuator by loosening the appropriate screws.

5. Position the lockout kit against the actuator outboard end. The locking shaft will insert and engage the lever end geometry.

Size 2 actuator: The standard size 2 lockout kit orientation shown in Figure 7 will accommodate the use of window-mount and end-mount digital valve controllers, positioners and accessories. This orientation requires removal of the locking pin in the direction of the bottom side of the actuator.

Size 3 actuator: For the window mounted DVC6200 digital valve controller, the size 3 lockout kit should be oriented such that locking pin removal is in the direction of the bottom side of the actuator. This mounting plate position provides necessary clearance with the integral supply pressure regulator. For the end-mount digital valve controller or accessory option, the size 3 lockout kit should be oriented as shown in the inset picture of Figure 7.

6. Loosely install the four flanged cap screws (key 53). Prior to tightening the fasteners, ensure the through-hole in the mounting plate is centered around the outside diameter of the locking shaft (key 50). Rotate the assembly by hand in the appropriate direction opposite of anticipated lever rotation to eliminate initial clearance among parts.
7. Tighten the cap screws (key 53) per the recommended torque values in Table 6.
8. Install the travel indicator (key 21) and travel indicator scale (key 19) to the lockout parts as illustrated in Figure 7.

WARNING

To avoid personal injury or property damage, ensure the travel indicator is installed correctly to coincide with the desired actuator action. Refer to Figure 4 for more information.

9. For normal actuator operation, remove the hairpin cotter pin (key 54) and locking pin (key 52) from the center pinhole of the mounting plate and reinstall these parts in the second pinhole for storage.

4.3 Operating the Locking Mechanism (Sizes 2 and 3)

To Lock the Actuator

1. With the actuator lever (key 14) against the up travel stop (spring-fail position), insert the locking pin (key 52) through the center pinhole of the mounting plate and through the pin hole in the locking shaft. Install the hairpin cotter pin (key 54) for retention.
2. Install the customer-supplied locking device to further prevent removal of the locking pin.

To Unlock the Actuator

1. Remove the customer-supplied locking device.
2. Remove the hairpin cotter pin (key 54) and locking pin (key 52) from the center pinhole of the mounting plate and reinstall these parts in the second pinhole for storage.

WARNING

To avoid personal injury or property damage, be aware the travel indicator scale (key 19) retains the locking shaft (key 50) during normal actuator operation. Removal of the travel indicator scale could allow the locking shaft to fall out in certain actuator orientations.

Section 5: Parts

5.1 Parts Ordering

When corresponding with your [Emerson sales office](#) about this equipment, refer to the serial number found on the actuator nameplate.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve and could cause personal injury and property damage.

Kits for Actuator Locking Mechanisms are available to keep the actuator in a locked position, the same as spring-fail, during maintenance. (Padlock is customer supplied). Not compatible with the declutchable handwheel on sizes 2 and 3 actuators. Some levers shipped with new 2052 actuators are not compatible with a lockout, and may need to be replaced with a compatible lever. Contact your [Emerson sales office](#) to confirm compatibility of the lever when adding a locking kit.

Figure 1. Fisher 2625 Volume Booster

W4727-1

Introduction

Scope of Manual

This instruction manual provides installation, operation, maintenance, and parts information for Fisher 2625 Series (2625, 2625SST, and 2625NS) volume boosters (figure 1). Refer to separate instruction manuals for information regarding the valve body, actuator, and other accessories.

Do not install, operate, or maintain a 2625, 2625SST, or 2625NS volume booster without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all of the contents of this manual, including all safety cautions and warnings. If you have any questions regarding these instructions contact your [Emerson sales office](#) before proceeding.

Description

The 2625 and 2625SST are certified for use in Safety Instrumented System (SIS) applications. Certification is by EXIDA Consulting LLC, a global provider of functional safety and control system security. SIS certification is identified on the product by the EXIDA logo on the 2625 nameplate.

The 2625, 2625SST, and 2625NS volume boosters are used in conjunction with a positioner on a throttling control valve to increase stroking speed. The booster has a fixed deadband (controlled by the seat-to-seat dimension of the supply and exhaust plugs) which is factory set during assembly and testing. In addition, the booster incorporates soft-seat construction and an integral bypass restriction to eliminate positioner saturation problems that can occur with volume boosters that do not have these features. Adjustment of the integral bypass restriction is necessary for system stability. This adjustment does not affect the deadband of the booster, but does permit the control valve to respond to small input signal changes from the positioner without sacrificing steady-state accuracy.

It also allows the booster to deliver high-volume output for fast stroking when large, rapid input signal changes occur.

The volume booster is used to improve stroking speed. If precision valve control is required, the use of a positioner is recommended. If the volume booster is used for on/off control, the integral bypass restriction on the volume booster must be closed (turned fully clockwise).

To facilitate diagnostic testing, connectors and piping may be installed with each 2625, 2625SST, and 2625NS volume booster.

The 2625NS volume booster is designed for nuclear power applications. The 2625NS construction includes materials that provide superior performance at elevated temperature and radiation levels.

The O-rings in the 2625NS are EPDM (ethylene propylene) and the diaphragms are EPDM/meta-aramid. EPDM demonstrates superior temperature capability and shelf life over nitrile. The meta-aramid diaphragm fabric demonstrates improved strength retention at elevated temperature and radiation conditions.

NOTICE

Use a clean, dry, oil-free air supply with instruments containing EPDM components. EPDM is subject to degradation when exposed to petroleum based lubricants.

Under the 10CFR50, Appendix B, quality assurance program, the 2625NS volume booster is qualified “commercial grade dedicated”. These can be supplied as 10CFR, Part 21 items.

Specifications

Specifications for the 2625, 2625SST, and 2625NS volume booster are listed in table 1. Information for an individual unit as it comes from the factory appears on the product nameplate.

Table 1. Specifications

Port Diameters⁽¹⁾

Supply Port: ■ 9.5 mm (0.375 inch) or ■ 12.7 mm (0.5 inch)

Exhaust Port: ■ 2.4 mm (0.094 inch)⁽²⁾, ■ 9.5 mm (0.375 inch) or ■ 12.7 mm (0.5 inch)

Input Signal

Positioner output

Maximum Input Signal Pressure

10.3 bar (150 psig)

Input to Output Pressure Ratio

Fixed at 1 to 1

Supply Pressure Ranges⁽³⁾

When used in conjunction with a positioner or other pneumatic accessory, always pipe the positioner and booster with one common supply through a Fisher 67D, 67DR, or MR95H regulator (see figure 3). A high-capacity filter, such as the Fisher 262K, should be installed in the supply line to the regulator. Supply pressure also must not exceed the maximum pressure rating of the actuator. Constructions are available in two maximum supply ranges.

When Normally Used With Diaphragm Actuators: Up to 2.8 bar (40 psig)

When Normally Used With Piston Actuators: Up to 10.3 bar (150 psig)

Nominal Deadband⁽⁴⁾

Percent of Positioner Output Span⁽⁶⁾:

2.4 mm (0.094 inch) exhaust port: 2%

9.5 mm (0.375 inch) exhaust port: 3.5%

12.7 mm (0.5 inch) exhaust port: 5%

Operative Temperature Limits^(3,4)

2625/2625SST

Standard: -40 to 71 °C (-40 to 160 °F)

High Temperature: 0 to 121 °C (32 to 250 °F)

2625

Low Temperature⁽⁵⁾: -60 to 65 °C (-76 to 149 °F)

2625NS: -40 to 93 °C (-40 to 200 °F)

Maximum Flow Coefficients

See table 2

Connections

Input Signal: 1/4 NPT

Supply and Output Signal: 3/4 NPT

Hazardous Area Classification

Complies with the requirements of ATEX Group II Category 2 Gas and Dust

 Ex h IIC Tx Gb
Ex h IIIC Tx Db

Maximum surface temperature (Tx) depends on operating conditions

Gas: T4, T5, T6

Dust: T85...T121

Meets Customs Union technical regulation TP TC 012/2011 for Groups II/III Category 2 equipment

Safety Instrumented System Classification

SIL3 capable - certified by exida Consulting LLC

Approximate Weight

Aluminum: 2.3 kg (5 pounds)

Stainless Steel: 4.8 kg (10.6 pounds)

Declaration of SEP

Fisher Controls International LLC declares this product to be in compliance with Article 4 paragraph 3 of the PED Directive 2014/68/EU. It was designed and manufactured in accordance with Sound Engineering Practice (SEP) and cannot bear the CE marking related to PED compliance.

However, the product *may* bear the CE marking to indicate compliance with *other* applicable EC Directives.

1. May be used in any combination.

2. Aluminum 2625 volume booster only.

3. The pressure/temperature limits in this document, and any applicable code or standard limitation should not be exceeded.

4. This term defined in ISA Standard S51.1

5. Low Temperature option only available with CUTR approval.

6. Zero psig to maximum supply.

Table 2. Maximum Flow Coefficients

PORT SIZE COMBINATIONS				SUPPLY PORT COEFFICIENTS	EXHAUST PORT COEFFICIENTS

Installation

⚠ WARNING

Always wear protective clothing, gloves, and eyewear when performing any maintenance procedures to avoid personal injury.

System damage may result if a volume booster is installed in a way that it can be physically damaged.

Personal injury or system damage may result when service conditions exceed booster or other equipment ratings. Exceeding the pressure specifications in table 1 may cause leakage, parts damage, or personal injury due to bursting of pressure-containing parts or explosion of accumulated gas.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

NOTICE

Do not use sealing tape on pneumatic connections. This instrument contains small passages that may become obstructed by detached sealing tape. Thread sealant paste should be used to seal and lubricate pneumatic threaded connections.

Note

Do not use separate pressure supplies for the volume booster and associated positioner.

The volume booster may not exhaust immediately upon loss of a separate pressure supply. However, if the system is in a transient state at the time of pressure supply loss or if changes to the booster's input signal are sufficient to overcome the deadband, the booster will exhaust.

A loss of a pressure supply (either separate or common) to a 3582 or 3610J positioner will cause the positioners output pressure (booster's input pressure) to decay.

Always pipe the positioner and the volume booster with one common supply. See figure 3 for typical installation examples. A 67D, 67DR, or MR95H regulator is required to provide sufficient capacity to supply both components. A high-capacity filter, such as the 262K, should be installed in the supply line to the 67D, 67DR, or MR95H regulator.

Mounting

The volume booster is typically nipple-mounted between the pneumatic supply source and the actuator, and may be used with piston or diaphragm actuators. Many actuators require larger casing or cylinder connections and modifications to allow the booster to deliver the higher volume output.

The booster may also be directly mounted to the actuator by using an actuator yoke mounting bracket (see figure 5) or casing mounting bracket.

Pressure Connections

NOTICE

Do not use sealing tape on pneumatic connections. This instrument contains small passages that may become obstructed by detached sealing tape. Thread sealant paste should be used to seal and lubricate pneumatic threaded connections.

The input signal connection is 1/4 NPT. The supply and output connections are 3/4 NPT (minimum pipe size recommended for nipple mounting is 1/2 NPT for 2625 and 3/4 NPT for 2625SST). Connections to the volume booster should be made as indicated in figure 2. Connections for two typical applications are shown in figure 3. Ensure that the piping is of proper size to meet the capacity demands of the booster and that you equip the actuator with properly sized input connections.

Figure 2. Volume Booster Sectional View

W0679-1

Figure 3. Typical Installations

B2372-1

Diagnostic Connections

To support diagnostic testing of valve/actuator/positioner packages, install connectors and hardware between the 2625, 2625SST, or 2625NS volume booster and the actuator. Typical connector installations are shown in figure 3.

The hardware used includes a 3/4 NPT pipe nipple, pipe tee, and pipe bushings with an 1/8 NPT pipe bushing for the connector. The connector consists of an 1/8 NPT body and body protector.

See separate instructions for diagnostic connections to the positioner.

Supply Pressure

Supply pressure must be clean dry air or noncorrosive gas. A high capacity filter, such as the 262K is recommended for use with the 2625 volume booster.

NOTICE

Use a clean, dry, oil-free air supply with instruments containing EPDM components. EPDM is subject to degradation when exposed to petroleum based lubricants.

⚠ WARNING

If a flammable or hazardous gas is to be used as the supply pressure medium, personal injury, property damage or equipment damage could result from fire or explosion of accumulated gas or from contact with hazardous gas. The optional pipe away vent construction should be used in applications using a flammable or hazardous gas as the supply pressure medium. This option will allow the flammable or hazardous gas to be collected or remotely vented to a safe location.

Exhaust Ports

Exhaust to the atmosphere is through exhaust ports in the side of the unit. Keep the exhaust ports free of any obstructions or foreign materials that might clog them.

The optional pipe away vent construction exhausts through a single 1/2 NPT port on the side of the unit. Remote vent piping can be installed in this port to route the booster exhaust to a desired remote vent or collection location.

Operating Information

The only operating requirement of the volume booster is the adjustment of the bypass restriction for stable actuator performance. Although systems with different characteristics may require different adjusting techniques, the following adjustment procedure is recommended when using the actuator for throttling control.

Note

When sizing the booster, select the lowest C_g that will meet the stroking speed specifications. Oversizing the booster in a closed loop may lead to stability problems, thus requiring the bypass to be opened so far that the booster will never operate.

Prior to operation, turn the bypass restriction adjusting screw (figure 2) four turns counterclockwise from the fully closed position. With the actuator in operation, slowly turn the restriction clockwise until the booster operates in response to large changes in the input signal, yet allows small changes to move the actuator without initiating booster operation.

If the actuator is to be used for on-off control, the restriction should be closed (turned fully clockwise).

Principle of Operation

Refer to figures 2 and 3.

Because of the restriction, large input signal changes register on the booster input diaphragm sooner than in the actuator. A large, sudden change in the input signal causes a pressure differential to exist between the input signal and the output of the booster. When this occurs, the diaphragms move to open either the supply port or the exhaust port, whichever action is required to reduce the pressure differential. The port remains open until the difference between the booster input and output pressures returns to within the deadband limits of the booster. With the bypass restriction adjusted for stable operation, signals having small magnitude and rate changes pass through the bypass restriction and into the actuator without initiating booster operation. Both the supply and exhaust ports remain closed, preventing unnecessary air consumption and possible saturation of positioner relays.

Maintenance

⚠ WARNING

Always wear protective clothing, gloves, and eyewear when performing any maintenance procedures to avoid personal injury.

Maintenance requires taking the volume booster out of service periodically. To avoid personal injury or equipment damage, disconnect or bypass any pressure lines to the booster, and vent any pressure locked in the unit before you begin maintenance.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

Diaphragm Assembly Replacement

Key numbers refer to figure 4.

1. Remove the six cap screws (key 15) from the perimeter of the spring case assembly (key 3), and lift off the assembly, taking care you do not lose the input spring (key 8) or the spring seat (key 9).
2. Remove the upper diaphragm (key 6), diaphragm spacer (key 2), diaphragm assembly (key 5), (which includes the lower diaphragm), and the O-rings (key 14). Inspect these parts for damage and replace if necessary.
3. Replace the O-rings (key 14) after coating with lubricant (key 21). Then replace the diaphragm assembly (key 5), diaphragm spacer (key 2), and the upper diaphragm (key 6).

Note

To ensure proper operation of the bypass restriction, make certain that the holes in the diaphragm and the bypass restriction are in line with the holes in the diaphragm spacer (key 2).

4. Install the spring case assembly (key 3) on the upper diaphragm (key 6). Make sure the spring seat (key 9) and the upper spring (key 8) are installed in the spring case assembly (key 3). Press on the bottom of the spring seat with

your finger. If the spring seat (key 9) does not move freely in the spring case assembly (key 3), remove the spring seat (key 9), and apply lubricant (key 23). Reinstall the spring seat (key 9) in the spring case assembly (key 3).

NOTICE

To avoid damage to the diaphragms, do not overtighten the screws.

- Replace the six cap screws (key 15) and tighten them in a crisscross manner.

Valve Assembly Replacement

Note

The distance between the exhaust port seat line on the upper valve (key 7C) and the supply port seat line on the lower valve and stem (key 7B) is critical to ensure the deadband requirements of the volume booster. This distance is set at the factory and is not field adjustable. If replacement is necessary, use the proper factory authorized repair kit listed in the parts section below. All components of the repair kits are factory set and tested and are not field adjustable.

For key numbers refer to figure 4.

Figure 4. Volume Booster Assembly Drawing

1. Remove the six cap screws (key 15) from the perimeter of the spring case assembly (key 3) and lift off the assembly, taking care you do not lose the upper spring (key 8) or the spring seat (key 9).
2. Remove the upper diaphragm (key 6), the diaphragm spacer (key 2), the diaphragm assembly (key 5), (which includes the lower diaphragm), and the O-rings (key 14).
3. Unscrew the valve assembly (key 7) from the body. The seat ring (key 7A) has a 1-1/2 inch hex for removal.
4. Apply lubricant (key 21) to the O-ring (key 7D), lubricant (key 23) to the lower valve and stem (key 7B), and sealant (key 20) to the thread of the seat ring (key 7A).
5. Install the valve assembly (key 7) into the body (key 1)—making sure the lower valve and stem (key 7B) engages over the lower spring (key 10)—and into the bottom plug (key 4).
6. Install the diaphragm assembly (key 5) onto the upper valve (key 7C).
7. Install the diaphragm spacer (key 2) onto the body (key 1).

Note

To ensure proper operation of the bypass restriction, make certain that the holes in the diaphragm and the bypass restriction are in line with the holes in the diaphragm spacer (key 2).

8. Make sure the O-rings (key 14) are installed in the diaphragm spacer (key 2) and coated with lubricant (key 21).
9. Install the upper diaphragm (key 6).
10. Install the spring case assembly (key 3) on the upper diaphragm (key 6). Make sure the spring seat (key 9) and upper spring (key 8) are installed in the spring case assembly. Press on the bottom of the spring seat with your finger. If the spring seat does not move freely in the spring case assembly, remove the spring seat, apply lubricant (key 23), and reinstall in the spring case assembly.

NOTICE

To avoid damage to the diaphragms, do not overtighten the screws.

11. Replace the six cap screws (key 15) and tighten them in a crisscross manner.

Installation of Diagnostic Connections

See figure 3 for part names and order of installation.

1. Before you assemble the pipe nipple, pipe tee, pipe bushings, actuator piping, and connector body, apply sealant to all threads.
2. Turn the pipe tee to position the connector body and body protector for easy access when doing diagnostic testing.

Parts Ordering

Whenever corresponding with your [Emerson sales office](#) about this equipment, mention the serial number of the volume booster. This serial number can be found on the nameplate (key 16, figure 4).

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher instrument. The use of components not manufactured by Emerson may void your warranty, might adversely affect the performance of the instrument, and could cause personal injury and property damage.

Introduction

Scope of Manual

This instruction manual provides information on installation, adjustment, maintenance, and parts ordering for the Type 3024C actuator (figure 1) for sizes 30 to 45 and 30E to 45E.

Note

This manual assumes throughout that the valve construction is “push-down-to-close.”

Do not install, operate, or maintain a 3024C actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

The 3024C direct acting (extends stem/air-to-close) actuator (figure 8) and the reverse acting (retracts stem/air-to-open) actuator (figure 9) are spring-opposed pneumatic diaphragm actuators that provide automatic throttling or on-off operation of sliding-stem control valves.

The actuator will position the valve plug in response to varying pneumatic loading pressure on the actuator diaphragm. Figure 2 shows the operation of an ATC (air-to-close) actuator and an ATO (air-to-open) actuator.

The 3024C ATC (air-to-close) actuator springs are located under the diaphragm plate and they fully retract the actuator stem for fail action upon loss of diaphragm casing pressure. The 3024C ATO (air-to-open) actuator springs are located on top of the diaphragm plate and they fully extend the actuator stem upon loss of diaphragm casing pressure. The actuator is mounted on the valve by means of a cast yoke.

The 3024C can be equipped with a side mounted handwheel if required (figure 10). An adjustable up travel stop can also be fitted (figures 11 and 12).

1. Effective diaphragm area at 0% valve travel from seat.

2. Based on zero operating pressure to the diaphragm and valve travel at 0% from valve seat. This does not consider limitations such as stem buckling load. Consult your [Emerson sales office](#) or Local Business Partner for details.

Table 4. Handwheel Specifications

ACTUATOR SIZE	HANDWHEEL DIAMETER		TURNS PER mm/INCH TRAVEL		RIM FORCE ^(1,2)		HANDWHEEL OUTPUT FORCE	
	mm	In.	mm	In.	N	lb	N	lb
30 and 30E	200	7.87	0.24	6.1	179	40	5000	1125
34, 34E, 40, and 40E	250	9.84	0.21	5.4	286	64	10,000	2250
45 and 45E	250	9.84	0.21	5.5	400	90	14,000	3150

1. Tangential handwheel force required to produce the handwheel output force shown.

2. Brass operating nut and stainless steel screw.

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operation to avoid personal injury.

To avoid personal injury and parts damage, do not apply pressure that exceeds the Maximum Operating Diaphragm Pressure (table 1) or produces a output thrust on the stem greater than the Maximum Actuator Stem Force (table 2 and 3). Use pressure-limiting or pressure-relieving devices to prevent the operating pressure from exceeding the Maximum Operating Diaphragm Pressure.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

When ordered, the valve configuration and construction materials were selected to meet particular pressure, temperature, pressure drop, and controlled fluid conditions.

Responsibility for the safety of process media and the compatibility of valve materials with the process media rests solely with the purchaser and end user. Since some valve body/trim materials combinations are limited in their pressure drop and temperature ranges, do not apply any other conditions to the valve without first contacting your Emerson Automation Solutions sales office.

If installing into an existing application, also refer to the WARNING at the beginning of the Maintenance section in this instruction manual.

A 3024C diaphragm actuator is normally shipped mounted on a valve. Refer to the appropriate valve instruction manual when installing the valve in the pipeline. If the actuator is shipped separately or if it is necessary to mount the actuator on the valve, perform the Actuator Mounting procedure given below. For information on mounting the positioner, refer to the appropriate positioner instruction manual.

Note

The 3024C actuators are designed to mount on push-down- to-close valves. Do not mount these actuators on any other type of valve without first contacting your [Emerson sales office](#).

Mounting the Actuator on the Valve

The following procedure describes how to mount a 3024C actuator on a push-down-to-close valve so that the actuator stem and valve stem thread engagement allows full travel and proper shut-off. Refer to table 4 and figures 6 and 7 for actuator dimensions. Key numbers referenced in the following steps are shown in figures 8 and 9.

1. Provide a temporary method of applying diaphragm air loading pressure to the diaphragm to move the actuator stem during adjustments.
2. Provide a vice or some other method of supporting the valve and the weight of the actuator during assembly.
3. Push the valve stem down until the valve plug is fully closed.
4. Screw the two stem locknuts (key 52) to the lower end of the valve stem thread.

Figure 4. Actuator Mounting Components for Assembly with a Valve

W8484-1

⚠ WARNING

When moving the actuator stem with diaphragm loading pressure use caution to keep hands and tools out of the actuator stem travel path. Personal injury and/or property damage is possible if something is caught between the actuator stem and other parts of the valve assembly.

Perform one of the following procedures as appropriate:

For a 3024C Air-To-Close Actuator with a Push-Down-to-Close Valve:

- a. Carefully place the actuator on the valve so that the yoke boss fits over the valve bonnet.
- b. Screw the yoke lock nut onto the bonnet and tighten.
- c. Lift the valve plug off the seat by the correct valve travel for the valve. This is stated on the nameplate or in table 1.
- d. Place the stem connector half (key 50) approximately halfway between the actuator and valve stems but observing the F dimension in table 5 so that any positioner lever (if fitted) is horizontal at mid-travel. Be sure that the actuator and valve stem threads are engaging the threads of the stem connector by at least the distance of one diameter of the stem.

NOTICE

Be sure that the length of the actuator stem and the valve stem in the connector (key 50) is equal to or greater than the diameter of that stem. Incomplete engagement of either the valve or actuator stem in the stem connector can result in stripped threads or improper operation.

In the following procedure do not rotate the valve plug while it is seated. This may damage the seating surface and cause excessive leakage. While making adjustments, use tools carefully to avoid damaging the valve stem. A damaged stem could cut the packing and allow leakage through the packing box.

- e. Install the other half of the stem connector and insert the socket screws and nuts and tighten them.
- f. Screw the two stem locknuts (key 52) up the valve stem to the stem connector and tighten. Do not over tighten.
- g. Slowly decrease and then increase the diaphragm pressure several times stroking the valve from the lower end to the upper end of the spring range.
- h. Apply air pressure to the diaphragm until the valve is in the closed position. Loosen the screws of the travel scale (key 26) and align it with the indicator on the stem connector.
- i. Stroke the valve full travel to ensure that the travel matches the valve travel on the travel indicator plate.
- j. If the valve travel is not correct, repeat the stem connector procedure. Remove the air pressure from the diaphragm, remove the stem connector and repeat steps c to i.

For a 3024C Air-to-Open Actuator with a Push-Down-to-Close Valve:

- a. Apply approximately 0.5 bar pressure above the upper setting of the spring pressure range to the bottom of the diaphragm. This positions the actuator stem (key 8) at the highest point. The spring range is stated on the nameplate or in table 3.
- b. Carefully place the actuator on the valve so that the yoke boss fits over the valve bonnet.
- c. Screw the yoke lock nut onto the bonnet and tighten.
- d. Lift the valve plug off the seat by the correct travel for the valve. The travel is stated on the nameplate or in table 1.
- e. Place the stem connector half (key 50) approximately halfway between the actuator and valve stems but observing the F dimension in table 5 so that any positioner lever (if fitted) is horizontal at mid-travel. Be sure that the actuator and valve stem threads are engaging the threads of the stem connector by at least the distance of one diameter of the stem.
- f. Install the other half of the stem connector and insert the socket screws and nuts and tighten them.
- g. Screw the two stem locknuts (key 52) up the valve stem to the stem connector and tighten. Do not over tighten.
- h. Slowly decrease and then increase the diaphragm pressure several times stroking the valve from the lower end to the upper end of the spring range.
- i. Remove all air pressure from the diaphragm so that the valve is in its closed position. Loosen the screws of the travel scale (key 26) and align it with the indicator on the stem connector.
- j. Stroke the valve full travel to ensure that the valve travel matches the valve travel on the travel indicator plate.

- k. If the valve travel is not correct repeat the stem connector procedure. Apply approximately 0.5 bar pressure above the upper setting of the spring range to the bottom of the diaphragm, remove the stem connector and then repeat steps d to j.

Note

When disassembling the stem connector on Air-to-Open constructions it is essential to apply enough air pressure to the underside of the diaphragm to lift the valve plug off its seat. This will ensure that all residual spring compression in the actuator is supported while the stem connector is removed.

Actuator Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced as necessary. The frequency of inspection and replacement depends upon the severity of the service conditions.

This section describes how the actuator can be completely disassembled and assembled. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job; then start to assemble at the appropriate step.

Key numbers refer to figures 8 and 9.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
 - Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
 - Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
 - Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
 - Vent the power actuator loading pressure and relieve any actuator spring precompression.
 - Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
 - The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
 - Check with your process or safety engineer for any additional measures that must be taken to protect against process media.
-

Disassembly

1. For complete disassembly, the positioner and all accessories (if attached) must be removed from the actuator. Follow appropriate removal procedures in the instruction manuals supplied with the positioner and accessories.

2. Bypass the control valve. For a top-loaded 3024C Air-to-Close actuator, reduce the diaphragm air pressure to zero and remove the piping or tubing from the connection in the upper diaphragm casing (key 16). For a bottom loaded 3024C Air-to-Open, apply air pressure to the diaphragm to open the valve.

Note

When disassembling the stem connector on Air-to-Open constructions, it is essential to apply enough air pressure to the underside of the diaphragm to lift the valve plug off its seat. This will ensure that all residual spring compression in the actuator is supported while the stem connector is removed.

3. Undo the stem connector by first slackening the valve stem locknuts and then removing the socket bolts.
4. Undo the yoke locknut on the valve bonnet and carefully lift the actuator off the valve. As you undo the yoke locknut, ensure that the actuator is properly supported. If the actuator is a bottom loaded Air-to-Open type, reduce the diaphragm pressure to zero and remove the piping or tubing from the connection in the lower diaphragm casing (key 1).
5. Slightly loosen all diaphragm casing cap screws (key 19 and 21). Remove the plastic hose (key 22). Unscrew the short and long diaphragm casing cap screws and nuts (keys 19, 20 and 21) alternately, until only the long casing cap screws (key 21) remain engaged. Then allow the remaining spring compression to be slowly released by alternately unscrewing the long casing cap screws.
6. When removing the diaphragm and actuator springs perform one of the following procedures as appropriate:

For a 3024C Air-to-Open Actuator (figure 9)

- a. Lift off the upper diaphragm casing (key 16), the casing spacer (key 29) and seal ring (key 30) if fitted (see figure 13), and remove the springs (Key 15).
- b. Using a strap wrench or soft-jawed vice, hold the actuator stem (key 8) and remove the travel stop nut (key 14).
- c. Remove the diaphragm plate (key 13), diaphragm (key 11), O-Ring (key 12), pressure plate (key 10) and the split ring halves (key 9).

For a 3024C Air-to-Close Actuator (figure 8)

- a. Lift off the upper diaphragm casing (key 16) and casing spacer (key 29) and seal ring (key 30) if fitted (see figure 13).
 - b. Using a strap wrench or soft-jawed vice, hold the actuator stem (key 8) and remove the travel stop nut (key 14).
 - c. Remove the pressure plate (key 10), O-ring (key 12), diaphragm (key 11), diaphragm plate (key 13) and the split ring halves (key 9).
7. Carefully slide the actuator stem (key 8) out of the bottom of the lower diaphragm casing (key 1) and set it on a protective surface to prevent damage to the O-ring sealing surface.
 8. Remove the bellows (key 31), if used.
 9. Unscrew the cheese head screws (key 7), then remove the bushing (key 6).
 10. With the actuator disassembled, inspect all parts for excessive wear and replace as necessary.

Assembly

This procedure assumes that the actuator is completely disassembled. If it is not, start the instructions at the appropriate step.

1. Before starting assembly, apply lithium grease (key 200) to the O-ring in the bushing (key 6 and key 12). Install the new bushing (key 6) and assemble with the cheese head screws (key 7) onto the lower diaphragm casing (key 1). Use a torque of 0.4 N•m (3 lbf•in).
2. Assemble the ring halves (key 9), pressure plate (key 10), O-ring (key 12), diaphragm (key 11) and diaphragm plate (key 13) on to the actuator stem as shown in figure 9 for Air-to-Open or figure 8 for Air-to-Close.
3. Apply thread locking adhesive (high strength) (key 201) to the thread on the upper end of the actuator stem, fit the travel stop nut (key 14) but do not tighten. Then perform one of the following procedures as appropriate.

For a 3024C Air-to-Open Actuator (figure 9)

- a. Carefully slide the actuator stem (key 8) (with the assembled parts) down through the bushing (key 6).
- b. Position the actuator springs (key 15) symmetrically on the diaphragm plate (key 13) as shown in figure 5.
- c. Install the upper diaphragm casing (key 16) so that the springs fit correctly over the seat bosses of the spring locator (key 17). Rotate the upper diaphragm casing along with the diaphragm/diaphragm plate assembly so that the air connection in the upper diaphragm casing is located directly above the air connection in the lower diaphragm casing. Then rotate the diaphragm without moving either the upper diaphragm casing or the diaphragm plate so that the diaphragm holes line up with those in the casings.
- d. Lift off the upper diaphragm casing and remove the springs. Tighten the travel stop nut (key 14) as follows: Sizes 30, 30E, 34, and 34E, tighten to 36 N•m (27 lbf•ft); Sizes 40, 40E, 45, and 45E, tighten to 87 N•m (64 lbf•ft).
- e. Replace the spring as previously.
- f. For actuator sizes 40E and 45E with 1.5 and 2 inch travels, a casing spacer is fitted between the upper and lower diaphragm casings. Place the casing spacer (key 29) on the diaphragm and then the gasket (key 30) as shown in figure 13.

For a 3024C Air-to-Close Actuator (figure 8)

- a. Position the actuator springs symmetrically on the spring locator (key 17) as shown in figure 5.
 - b. For actuator sizes 40E and 45E with 1.5 and 2 inch travels, a casing spacer (key 29) is fitted between the upper and lower diaphragm casings. Place the gasket (key 30) on the lower casing and then the casing spacer (key 29) as shown in figure 13.
 - c. Carefully slide the actuator stem with the assembled parts down through the bushing and position it so that the springs fit correctly over the seat bosses on the upper side of the diaphragm plate (key 13). Rotate the diaphragm (key 11) without moving the diaphragm plate (key 13) so that the diaphragm holes line with the lower diaphragm casing holes.
 - d. Tighten the travel stop nut (key 14) as follows: Sizes 30, 30E, 34 and 34E tighten to 36 N•m (27 lbf•ft); Sizes 40, 40E, 45 and 45E tighten to 87 N•m (64 lbf•ft).
4. Install the upper diaphragm casing (key 16) so that the air connection is located directly above the air connection in the lower diaphragm casing (key 1). Using the long cap screws (key 21) and hex nuts (key 20) first, and then the shorter cap-screws (key 19) and hex nuts (key 20), bolt the two diaphragm casings together. Fit the safety plastic hose (key 22) over the exposed thread of the long cap-screws (key 21).

NOTICE

Over tightening the diaphragm cap screws and nuts can damage the diaphragm. Do not exceed the torque of 13 N•m (10 lbf•ft) for sizes 30, 30E, 34 and 34E and 17 N•m (12 lbf•ft) for sizes 40, 40E, 45, and 45E.

Figure 5. Fisher 3024C Spring Arrangements

Note

Be sure to use the long cap screws (key 21) first, installing them on opposite sides of the diaphragm casing. Tighten them evenly, using a criss-cross pattern to ensure a proper seal.

5. Mount the actuator on the valve in accordance with the Installation Procedures.

Changing the Actuator Action

The actuator can be changed from a 3024C Air-to-Open to a 3024C Air-to-Close action or vice versa. Remove the pressure plate, diaphragm, O-ring, diaphragm plate, travel stop nut, springs, spring locator, self tapping screws and vent assembly (keys 10, 11, 12, 13, 14, 15, 17, 18 and 23) and reinstall them for the appropriate action. Follow the instructions in the section on Assembly on page 8.

Side-Mounted Handwheel

A side-mounted handwheel assembly (figure 10) is usually used as a manual operator. When mounted on an Air-to-Close 3024C actuator, turning the handwheel clockwise always closes the valve. When mounted on an Air-to-Open actuator, turning the handwheel clockwise always opens the valve. A lever (key 101, figure 10) on the handwheel assembly opens or closes the valve by moving the valve stem.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as is necessary to accomplish the required maintenance; then begin the assembly at the appropriate step.

Refer to figure 10 for key numbers.

Disassembly

1. If desired, the handwheel assembly can be removed from the actuator yoke. To do this, remove the eight hex cap screws (key 113) that hold the assembly to the yoke.
2. Loosen the lock (key 115) that secures the drive screw assembly (key 103).
3. Remove the retaining ring (key 110) and screw out the drive screw assembly (key 103).
4. Remove the retaining ring (key 108) and drive out the pivot pin (key 104).
5. Remove the bushings (key 107) from the body (key 100).
6. There is a cap screw (key 111), hex nut (key 112) and spacer (key 105) that hold the two levers (key 101) together. Remove the cap-screw and hex nut and the two levers can be separated in order to remove the operating nut (key 102).

Assembly

1. Assemble the operator nut (key 102), the two levers (key 101) and the spacer (key 105) using the cap-screw (key 111) and hex nut (key 112).
2. Install the bushings (key 107) in the body (key 100).
3. Attach the levers (key 101) to the body (key 100) using the pivot pin (key 104) and the retaining ring (key 108).
4. Apply lithium grease (key 200) to the drive screw assembly (key 103) and screw it on to the operating nut (key 102).
5. Install the retaining ring (key 110) to secure the collar to the body (key 100).

6. If the handwheel assembly was removed from the actuator yoke, position the assembly within the yoke so that the eight mounting holes on the assembly align with those on the yoke and fit the cap-screws (key 113) tightening to 28 N•m (20 lbf•ft). Should difficulty be experienced fitting the levers (key 101) over (for ATC) or under (for ATO) the actuator/valve stem connector, then partially stroke the actuator/valve by applying air pressure to the actuator diaphragm.

Adjustable Travel Stops

The adjustable up travel stop (figures 11 and 12) limits the actuator stroke in the upward direction (limits retraction of the actuator stem).

⚠ WARNING

When performing the following adjustment procedures, take care to avoid injury when positioning components.

For Sizes 30, 30E, 34, 34E, 40, and 40E

1. Relieve the air pressure on the diaphragm. Loosen the hex nut (key 25) and turn the adjuster (key 24) clockwise into the diaphragm case to move the actuator stem downward or counter-clockwise to allow the actuator stem to move upward. Since the valve has push-down-to-close action, full opening can be restricted. Check the actuator travel and then tighten the hex nut (key 25).

Note

The travel stop hex nut (key 25) has an elastic stop on its underside to provide an air seal around the travel stop thread. It is therefore important, before slackening this nut, to release any air pressure on the diaphragm.

For Sizes 45 and 45E

The adjustable up travel stop for the sizes 45 and 45E is shown in figure 12. For sizes 45 and 45E, the adjustable up travel stop cannot be used with a side mounted handwheel.

1. Remove the screws (key 41) and nuts (key 42) which hold the protective covers (key 40) to the actuator yoke and remove the covers.
2. Loosen the machined cheese head screw (key 37) and turn the adjustment nut (key 38) clockwise into the bushing (key 36) to increase travel or counter-clockwise to shorten the actuator travel.
3. Check the actuator travel and then tighten the machined cheese head screw (key 37).
4. Assemble the protective cover plates (key 40) to the actuator yoke with the screws (key 41) and nuts (key 42) taking care to ensure that there is no gap between the cover plate and the diaphragm casing.

Figure 6. Actuator Dimensions

1Q57491

Actuator Dimensions

Refer to figures 6 and 7 and table 5 for dimensions.

Table 5. Dimensions

Actuator Size	Valve Travel	Yoke Boss, Inches	C	E	F ⁽¹⁾	AR	Js	Hs	M (ATO)	M (ATC)
			Millimeters							
30	16 mm	2-1/8 (54 mm)	215	370	140	105	205	280	185	80
34	16 mm	2-1/8 (54 mm)	315	400	140	105	250	280	185	80
40	32 mm	2-13/16 (71 mm)	315	420	170	133	250	280	210	100
45	32 mm	2-13/16 (71 mm)	420	450	170	133	250	280	210	100
Inches										
30E	0.75	2-1/8	8.5	14.6	5.6	4.7	8.1	11.0	7.3	3.1
34E	0.75	2-1/8	12.4	15.8	5.6	4.7	9.8	11.0	7.3	3.1
40E	1.125	2-13/16	12.4	17.9	8.1	6.6	9.8	11.0	9.6	5.5
40E	1.5	2-13/16	12.4	18.9	8.3	6.6	---	---	---	---
40E	2	2-13/16	12.4	18.9	8.5	6.2				
45E	1.125	2-13/16	16.5	19.3	8.1	6.6	9.8	11.0	9.6	5.5
45E	1.5	2-13/16	16.5	20.1	8.3	6.6	---	---	---	---
45E	2	2-13/16	16.5	20.1	8.5	6.2				

1. This is the distance between the base of the yoke to the centre of the stem connector at the fully-up position. This ensures the positioner feedback arm, if fitted, is horizontal at mid-travel.

Figure 7. Actuator Dimensions with Handwheel

Parts Ordering

Each actuator has a serial number stamped on the nameplate (figure 2 and key 34 on figures 8 and 9). Refer to the serial number when ordering replacement parts or when corresponding with your [Emerson sales office](#) for technical assistance.

⚠ WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Introduction

Scope of Manual

This instruction manual provides information on installation, adjustment, maintenance, and parts ordering for the Fisher 3025 actuators in sizes 1 and 2. Refer to separate instruction manuals for information about the valve positioner and other accessories used with these actuators.

Do not install, operate, or maintain a 3025 actuator without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

3025 Actuator

Maximum Diaphragm Casing Pressure ⁽¹⁾	bar	4	
	Psig	58	
Temperature Capabilities	°C	-30 to 82°C	
	°F	-22 to 180°F	
Pressure Connections (internal)		1/2 NPT	
		3/4 NPT	
		1 NPT	
Approximate Actuator Weights	kg	210 to 360	370 to 480
	lb	465 to 795	815 to 1,060
Approximate Side Handwheel Weights	kg	100	70
	lb	220	150
Maximum Allowable Output Thrust ⁽¹⁾	N	52,910	87,750
	lbs	11,895	19,725

1. Normal operating diaphragm pressure must not exceed maximum diaphragm casing pressure and must not produce a force on the actuator stem greater than the maximum allowable output thrust or the maximum allowable valve stem load. Contact your [Emerson sales office](#) with questions concerning maximum allowable valve stem load.

Description

The Fisher 3025 spring-opposed diaphragm actuators position the valve plug in the valve body in response to varying controller or valve positioner pneumatic output signals applied to the actuator diaphragm. They can be specified either direct or reverse acting. The 3025 size 1 actuator offers 203.2 mm (8 in) maximum travel. The 3025 size 2 actuator provides 139.7 mm (5.5 in) maximum travel.

The 3025 actuator can be equipped with a side-mounted handwheel assembly. It is usually used as an auxiliary manual actuator. Casing-mounted adjustable up and down travel stops are also available on this actuator.

Figure 2. Schematic of Fisher 3025 Actuator in Reverse and Direct Acting

Specifications

Refer to table 1 for Specifications of the 3025 actuator. See the actuator nameplate for specific information about your actuator.

Installation

⚠ WARNING

Always wear protective gloves, clothing, and eyewear when performing any installation operations to avoid personal injury.

Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

If installing into an existing application, also refer to the **WARNING** at the beginning of the Maintenance section in this instruction manual.

Key number locations are shown in figures 5 through 15, unless otherwise noted. Also, refer to figure 4 for location of parts.

NOTICE

To avoid parts damage, do not use an operating pressure that exceeds the Maximum Diaphragm Casing Pressure of 4 bar (58 psi) or produces a force on the actuator stem greater than the Maximum Allowable Valve Stem Load.

- **Valve/Actuator Assembly:** If the actuator and valve are shipped together as a control valve assembly, it has been adjusted at the factory, and may be installed in the pipeline. After installing the valve in the pipeline, refer to the Loading Connection procedures.
- **Actuator Mounting:** If the actuator is shipped separately or the actuator has been removed from the valve, it is necessary to mount the actuator on the valve before placing the valve in the pipeline. Refer to the following actuator mounting procedures before placing the valve in service.
- **Positioner:** If a positioner is installed, or is to be installed on the actuator, refer to the positioner instruction manual for installation. During the adjustment procedures, it will be necessary to provide a temporary loading pressure to the actuator diaphragm.

Lifting Actuator Assembly

⚠ WARNING

To avoid personal injury or equipment damage, use proper lifting and rigging practices while lifting the actuator assembly. For all mounting procedures use an adequately sized lifting and rigging equipment to handle the actuator and any attached accessories. Use caution during lifting and handling to prevent slippage, swinging, faulty equipment connections, or sudden shock loads.

To avoid personal injury or equipment damage, do not lift or support a complete valve and actuator assembly or any attached piping using the two threaded holes provided on the actuator. The threaded holes are provided for lifting of the actuator and accessories only.

NOTICE

Care must be taken when lifting the actuator assembly to ensure all accessories and tubing are not damaged in the process. Accessories and tubing may need to be removed prior to lifting to prevent damage and properly reinstalled before use.

Figure 3. Threaded Holes for Hoist Rings

The two threaded holes (M16x2 for Size 1 actuator or M20x2.5 for Size 2 actuator) located on the actuator protective cap can be used to install hoist rings and lift the actuator assembly with appropriate lifting and rigging equipment. The actuator assembly weight is provided in table 1. Consult the appropriate actuator accessory instruction manuals for the weight of each additional component.

Mounting the Actuator on the Valve

NOTICE

If the valve stem is allowed to remain in the up position (towards the actuator) during mounting, it can interfere with the actuator mounting, possibly damage valve stem threads or bend the valve stem. Be sure the valve stem is pushed down (into the valve body), away from the actuator while mounting.

⚠ WARNING

When moving the actuator stem with loading pressure applied, exercise caution to keep hands and tools out of the actuator stem travel path. If the loading pressure is accidentally disconnected, personal injury and property damage may result if something is caught between the actuator stem and other control valve parts.

Provide a temporary method of applying diaphragm loading pressure to the diaphragm to extend the actuator stem during bench set spring adjustments.

1. Provide a vise or some other method of supporting the valve and the weight of the actuator during assembly. For direct or reverse acting valves, push the valve stem down away from the actuator while mounting the actuator.
2. Screw the stem locknuts all the way onto the valve stem.
3. Lift or hoist the actuator onto the valve bonnet:

FISHER VALVE & ACTUATOR INSTRUCTION MANUALS

3025 Actuator

September 2022

Instruction Manual

D104736X012

- a. For size 3-9/16 yoke boss, slowly lower the actuator down onto the valve. As the yoke passes over the end of the valve stem, place the yoke locknut over the valve stem. Continue to lower the actuator while guiding the valve stem into the opening in the end of the actuator stem. Once the actuator is in place, screw the yoke locknut onto the valve bonnet and tighten the locknut.
- b. For 5 and 5H yoke boss, slowly lower the actuator down onto the valve while guiding the valve stem into the opening in the end of the actuator stem. Once the actuator is in place, insert the cap screws and tighten the hex nuts, securing the actuator to the bonnet.

Figure 4. Actuator Mounting Components for 3025 Actuator

Installing the Stem Connector Assembly

When installing the stem connector assembly (key 26), the actuator and valve stem threads should engage the threads of the stem connector by the distance equal to the diameter of the stem.

⚠ WARNING

Install the stem connector securely before a positioner is mounted to the actuator and pressurized, using only a regulator-controlled air supply, not the positioner, to move the actuator stem.

To avoid personal injury or property damage, keep hands and tools out of the actuator stem travel path while applying loading pressure to move the actuator stem in the following steps.

NOTICE

To avoid damaging the seating surfaces, do not rotate the valve plug while it is seated. Exercise care while installing the stem connector assembly to avoid damage to the valve plug stem and valve stem threads.

Note

Replacement stem connectors are an assembly of two stem connector halves, cap screws, and a spacer between the connector halves. Remove the spacer and discard, if present, before clamping the actuator and valve stems together. Use only a mated pair of stem connectors.

1. If the actuator is equipped with a side-mounted handwheel, be sure that it is in the neutral position. If the actuator is equipped with casing-mounted travel stops, be sure that they do not limit the actuator travel.
2. If necessary, push the valve stem down so that it is touching the seat ring on direct-acting valves. For reverse acting valves, push the stem down to the open position.
3. If necessary, screw the valve stem locknuts down, away from the connector location.
4. Perform one of the following procedures (a or b as appropriate):
 - a. **For direct acting actuator**, increase slowly the diaphragm pressure until the actuator stem (key 6) moves down the specified travel.
 - b. **For reverse acting actuator**, set the diaphragm loading pressure to approximately 0.5 bar (7 psi) over the upper bench set pressure. Then release slowly the diaphragm pressure until the actuator stem (key 6) moves down the specified travel.
5. Place the stem connector half with the upper threaded hole fully engaged onto the actuator stem and align the actuator stem and valve stem with threads from both stems mated root-to-crest with the stem connector. A slight change to loading pressure may be necessary to align the threads. If the actuator is a size 2 equipped with a side-mounted handwheel, ensure that the anti-rotation plate (key 151) is pointed towards the neutral indicator (key 108) and that the holes in the anti-rotation plate are aligned with the tapped holes on the top of the stem connector half.
6. Install the other half of the stem connector and insert the cap screws and tighten them while ensuring even spacing between the stem connector halves on all sides. If installing a positioner, also attach the feedback bracket at the same time.
7. Screw the valve stem locknuts up against the stem connector. If the actuator is a size 2 equipped with a side-mounted handwheel, install the 4 cap screws (key 131) of the anti-rotation plate and tighten them. Verify that the pointer of the anti-rotation plate (key 151) is aligned with the neutral indicator (key 108).
8. Slowly stroke the actuator and verify full rated travel is achieved.

9. Be sure that the valve is in the closed position. Loosen the screws on the travel indicator scale (key 29) and align it with the travel indicator (key 30).
10. If the actuator is a size 2 equipped with a side-mounted handwheel, rotate the handwheel full travel to ensure that the travel of the side-mounted handwheel matches the rated valve travel on the nameplate. If travel is not correct, refer to the assembly procedures in the Side-Mounted-Handwheel Assembly for Size 2 Actuator Maintenance section to adjust the handwheel travel.
11. Stroke the actuator full travel to ensure that the travel matches the rated valve travel on the nameplate. If valve travel is not correct, repeat the stem connector procedure.

Loading Connection

The loading pressure connections are made at the factory if the valve, actuator, and positioner come as a unit. Keep the length of tubing or piping as short as possible to avoid transmission lag in the control signal. If a volume booster, valve positioner or other accessory is used, be sure that it is properly connected to the actuator. Refer to the positioner instruction manual or other manuals as necessary.

For actuators shipped separately or whenever the actuator pressure connections are installed, use the following steps:

1. Connect the loading pressure piping to the NPT internal connection in the diaphragm casing.
2. Cycle the actuator several times to be sure that the valve stem travel is correct when the correct pressure ranges are applied to the diaphragm.

WARNING

If valve stem travel appears to be incorrect, refer to the Stem Connector Assembly procedures at the beginning of this section. To avoid personal injury or product damage, do not place the valve into service if it is not reacting correctly to diaphragm loading pressure changes.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced when necessary. The frequency of inspection and replacement depends on the severity of service conditions.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Always wear protective gloves, clothing, and eyewear when performing any maintenance operations to avoid personal injury.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.
- The valve packing box may contain process fluids that are pressurized, *even when the valve has been removed from the pipeline*. Process fluids may spray out under pressure when removing the packing hardware or packing rings, or when loosening the packing box pipe plug.
- Check with your process or safety engineer for any additional measures that must be taken to protect against process media.

The maintenance instructions are divided into several sections: Actuator Maintenance, Side-Mounted Handwheel Assembly for Size 1 Actuator, Side-Mounted Handwheel Assembly for Size 2 Actuator, and Casing-Mounted Travel Stops.

Actuator Maintenance

This procedure describes how the actuator can be completely disassembled and assembled. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job; then, start the assembly at the appropriate step.

Key numbers refer to figures 5 through 10. Figures 5 and 6 show the Size 1 actuator for travel up to and including 139.7mm (5.5 inch), figures 7 and 8 show the Size 1 actuator for travel above 139.7mm (5.5 in) and up to 203.2mm (8 inch), figures 9 and 10 show the Size 2 actuator.

It may be necessary to apply a temporary loading pressure to the actuator during the disassembly.

Actuator Disassembly

Isolate the control valve from the line pressure, release pressure from both sides of the valve body, and drain the process media from both sides of the valve. Also shut off all pressure lines to the power actuator, release all pressure from the actuator. Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

1. If equipped, remove the tubing or piping from the connection in the diaphragm casing(s).
2. If equipped with adjustable travel stops, refer to the disassembly procedures in the Casing-Mounted Travel Stops Maintenance section to remove travel stop parts
3. **For reverse acting actuator only:** slightly pressurize the actuator diaphragm until movement of the actuator stem is detected and the spring force applied to the stem connector is relieved.

⚠ WARNING

To avoid personal injury due to the sudden uncontrolled movement of parts, do not loosen the stem connector cap screws when the stem connector has spring force applied to it.

4. Separate the stem connector by loosening the stem locknuts (keys 27 and 28) and unscrewing the two stem connector cap screws. **For reverse acting actuator only:** slowly exhaust the diaphragm pressure.
5. If necessary, separate the actuator from the valve body by removing the yoke locknut or the bolts.
6. **For direct acting actuator only:** it will be necessary to separate the actuator from the yoke (key 1) or from the side-mounted handwheel if equipped. If equipped with side-mounted handwheel, refer to the disassembly procedures in the Side-Mounted-Handwheel Maintenance section to separate the actuator from the side-mounted handwheel. For actuator without side-mounted-handwheel, remove the cap screws (key 24) of the yoke and lift off the actuator.
7. Remove the cap screws (key 24) of the protective cap (key 5) and lift off the protective cap.

⚠ WARNING

To avoid personal injury from the pre-compressed spring force thrusting the diaphragm casing away from the actuator, relieve the spring compression (step 8 below).

8. Relieve the spring compression by unscrewing alternately and slowly the 4 spring adjusting screws (key 16).

NOTICE

Be careful when pulling the threads of the actuator stem through the casings to avoid damaging the bushing (key 20) and O-ring (key 19).

9. Remove the cap screws and nuts (keys 22 and 23) of the spring casing (key 3) and lift off the spring casing.
10. Remove the spring plate (key 15) and actuator spring(s) (keys 13 and 14).
11. For size 2 actuator only: remove the cap screws and nuts (keys 22 and 23) of the air supply casing (key 2) and pull off the air supply casing. Unscrew the actuator stem pieces to separate the 2 diaphragm plates (key 8).
12. Lift off the stems and diaphragm plate assembly.
13. Unscrew the actuator stem pieces. Inspect diaphragm (key 17) and O-ring (key 18) and replace if necessary.
14. Inspect bushings (key 20), O-ring (key 19) and replace if necessary.

Table 2. Actuator Assembly Recommended Torque Values

DESCRIPTION, KEY NUMBER	ACTUATOR SIZE	THREAD SIZE, INCH	TORQUE	
			N • m	Lbf • ft
Actuator stems, keys 6, 9, 10, 12	1 and 2	1-1/2-12	300	221
Yoke and protective cap, key 24	1	M16x2	195	144
	2	M20x2.5	380	280
Diaphragm casing, keys 22 and 23 ⁽¹⁾	1 and 2	M10x1.5	32	24
Spring adjusting screws, key 16	1 and 2	M30x3.5	185	136
Valve stem connector cap screws, key 26 ⁽²⁾	1 and 2	1/2-13	92	68
Handwheel to casing, key 125	1	M16x2	195	144
	2	M20x2.5	380	280
Handwheel housing, keys 126 and 127	1	M16x2	150	111
Handwheel stem connector, key 124	2	1/2-13	92	68

1. Observe tightening patterns and procedure described in the appropriate Actuator Assembly section.
2. Torque values when lithium grease is used on the threads.

Actuator Assembly

Refer to table 2 as appropriate.

1. If removed, coat the bushings (key 20) with lithium grease (key 50) and slide them into the casings.
2. Coat the O-ring(s) (key 19) with lithium grease (key 50) and place into the air supply casing (key 2) and for size 2 actuator into the middle casing (key 4).
3. Ensure that the pins (key 21) are installed in the diaphragm plate (key 8) and spring plate (key 15).
4. Install the travel stop (key 11) on the actuator upper stem end (key 12) for reverse acting actuator or on the actuator lower stem end (key 6) for direct acting actuator, apply thread lock (key 52) to the threads and tighten this assembly into the stop stem (key 10) to 300 N • m (221 lbf • ft).
5. Perform one of the following procedures (a or b as appropriate):
 - a. For size 1 actuator: assemble the actuator lower stem end (key 6) for reverse acting actuator or the actuator upper stem end (key 12) for direct acting actuator, the thrust plate (key 7), the o-ring (key 18), the diaphragm (key 17), the diaphragm plate (key 8). Apply thread lock (key 52) to the actuator stem threads and install the stop stem assembly (keys 10, 11 and 6 or 12) and tighten to 300 N • m (221 lbf • ft). If equipped with a side-mounted handwheel, the pin hole in the lower actuator stem (key 6) shall be aligned with the middle of 2 bolt holes of the

diaphragm and it might be necessary for a good alignment to fully tighten the stem and diaphragm plate stem assembly only when the actuator is installed on the side-mounted handwheel with the pin (key 146) inserted through the sleeve and actuator stem. Then place the stem and diaphragm plate assembly in the air supply casing (key 2). Align the holes of the diaphragm with the holes of the casing and if equipped with side-mounted handwheel align the hole in the lower actuator stem (key 6) with the hole in the sleeve (key 101).

- b. For size 2 actuator: first assemble the parts located in the air supply casing (key 2): assemble the actuator lower stem (key 6) for reverse acting actuator or the actuator upper stem end (key 12) for direct acting actuator, the thrust plate (key 7), the O-ring (key 18), the diaphragm (key 17), the diaphragm plate without pin (key 8). Apply thread lock (key 52) to the actuator stem threads and tighten the middle stem (key 9) to 300 N•m (221 lbf•ft). Install this assembly in the air supply casing (key 2). Place the middle casing (key 4) with the bushing (key 20) towards the air supply casing (key 2) and with the vent (key 25) connection diametrically opposed to the air connection of the air supply casing (key 2). Install the cap screws and nuts (keys 22 and 23) and tighten slightly. Lift up the stem and diaphragm plate assembly and install the second thrust plate (key 7), O-ring (key 18), diaphragm (key 17) and diaphragm plate (key 8). Align the holes of the diaphragm with the holes of the casing. Apply thread lock (key 52) to the thread of the middle stem (key 9) and install the stop stem assembly (keys 10, 11 and 6 or 12) and tighten to 300 N•m (221 lbf•ft).

NOTICE

Be careful when pulling the threads of the actuator stem through the casings to avoid damaging the bushing (key 20) and O-ring (key 19).

6. Install the actuator spring(s) (keys 13 and 14).
7. Apply anti-seize lubricant (key 51) into the 4 bores of the spring plate (key 15) and install the spring plate with the bores aligned with the air connection of the air supply casing (key 2).
8. Place the spring casing (key 3) with the vent connection diametrically opposed to the air connection of the air supply casing (key 2). Ensure that the 4 tapped holes of the spring casing flange are aligned with the 4 bores on the spring plate (key 15).
9. Install the cap screws and nuts (keys 22 and 23). Tighten the diaphragm casing cap screws and nuts in the following manner. For the size 2 actuator tighten the cap screws and nuts of the 2 diaphragm casing joints.
10. The first 4 bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these 4 bolts to 16 N•m (12 lbf•ft).
11. Tighten the remaining bolts in a clockwise, criss-cross pattern to 16 N•m (12 lbf•ft).
12. Repeat this procedure by tightening 4 bolts, diametrically opposed and 90 degrees apart, to a torque of 32 N•m (24 lbf•ft).
13. Tighten the remaining bolts in a clockwise, criss-cross pattern to 32 N•m (24 lbf•ft).
14. After the last bolt is tightened to 32 N•m (24 lbf•ft), all of the bolts should be tightened again to 32 N•m (24 lbf•ft) in a circular pattern around the bolt circle.
15. Once completed, no more tightening is recommended.
16. Coat the threads of the spring adjusting screws (key 16) with anti-seize lubricant (key 51). Be sure that the 4 bores into the spring plate are aligned with the threaded holes of the spring casing. Then install and screw alternately and slowly the 4 cap screws to compress the spring(s). Tighten to the appropriate torque shown in table 2.
17. Place the protective cap (key 5) onto the casing, insert the cap screws (key 24) and tighten to the appropriate torque as shown in table 2.
18. If equipped with a side-mounted handwheel, refer to the assembly procedures in the Side-Mounted Handwheel Maintenance section.
19. Lift the actuator and place it on the yoke (key 1), insert the cap screws (key 24) and tighten to the appropriate torque as shown in table 2.

20. Install the vent(s) (key 25) on the casing(s).
21. If equipped with adjustable travel stops, refer to the assembly procedures in the Casing-Mounted Travel Stops Maintenance section.
22. Mount the actuator onto the valve in accordance with the procedures in the Installation section.

Side-Mounted Handwheel for Size 1 Actuator

A side-mounted handwheel (figure 11) is normally used as a manual actuator. The handwheel can be mounted in either of two position orientations so that, regardless of valve plug action, counter-clockwise rotation always opens the valve.

Instructions are given below for complete disassembly and assembly of the side-mounted handwheel assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

Key numbers are shown in figure 11.

Disassembly for Size 1 Side-Mounted Handwheel

1. Complete steps 1 through 5 of the disassembly portion of the Actuator Maintenance section.
2. Unscrew the pointer (key 149) from the sleeve (key 101). Remove the cap screws (key 24) of the yoke and lift off the actuator and handwheel assembly.
3. Unscrew the 6 cap screws (key 127). Remove the gear case and handwheel assembly.
4. If necessary, remove the handwheel housing (key 102) by unscrewing the 4 cap screws (key 125).
5. Turn the handwheel so that the sleeve (key 101) extends out of the bottom of the worm gear (key 112). Do not lose the key (key 111).
6. Loosen the set screws (key 128) of the retaining flange (key 1120). Unscrew the 2 cap screws (key 126) and remove the retaining flange. Lift out the retainer (key 115), the thrust bearings (key 113) and the worm gear (key 112).
7. The worm shaft (key 116) and associated parts can be removed in order to replace or lubricate them. First, loosen the set screw (key 148), unscrew the handwheel cap (key 122) and remove the handwheel (key 121). Do not lose the small ball or spring (keys 142 and 143).
8. Loosen the two set screws (key 129) and unscrew the two worm retainers (keys 119 and 120). The ball bearings (key 117) will come out with the retainers. Remove the worm shaft (key 116).

Assembly for Size 1 Side-Mounted Handwheel

1. Pack the ball bearings (key 117) with lithium grease (key 50) and insert one ball bearing in the back worm retainer (key 120).
2. Thread the back worm retainer and ball bearing (keys 50 and 120) into the gear case (109). Align the set screw slot in the worm retainer with the set screw hole in the gear case, insert the set screw (key 129) and tighten.
3. Coat the worm shaft (key 116) threads with lithium grease lubricant (key 50) and slide the shaft into the gear case (key 109) so that the end of the shaft fits snugly in the back worm retainer.
4. Insert the bearing in the front worm retainer (key 119) and thread the retainer and ball bearing into the gear case. Align the set screw slot in the retainer with the set screw hole in the gear case, insert the set screw (key 129) and tighten.
5. Put the spring and ball (keys 142 and 143) in the handwheel (key 121). Slide the handwheel onto the worm shaft (key 116). Thread the handwheel cap (key 122) onto the worm shaft, insert the set screw (key 148) in the cap and tighten.
6. Pack the 2 thrust bearings (key 113) with lithium grease (key 50). Install one thrust bearing; then install the worm gear (key 112), followed by the second thrust bearing and the bearing retainer (key 115).

7. Coat the key (key 111) with lithium grease (key 50) and install it on the retaining flange (key 110).
8. Insert the set screws (key 128) in the retaining flange (key 110). Install the 2 cap screws (key 126) and tighten to the appropriate torque as shown in table 2. Adjust the set screws (key 128) to eliminate free play in the bearings. Note over-tightening the set screws will make handwheel operation difficult.
9. Coat the sleeve (key 101) threads and slot with lithium grease (key 50), slide the sleeve into the retaining flange with the slot aligned with the key (key 11), turn the handwheel and feed the sleeve through the worm gear. Continue turning the handwheel until the threads of the sleeve are fully engaged in the gear case.
10. If removed, install the handwheel housing (key 102) on the actuator, insert the cap screws (key 125) and tighten to the appropriate torque as shown in table 2.
11. Install the gear case and handwheel assembly on the handwheel housing (key 102), insert the cap screws (key 127) and tighten to the appropriate torque as shown in table 2.
12. Place the handwheel and actuator assembly on the yoke, insert the cap screws (key 125) and tighten to the appropriate torque as shown in table 2.
13. Install the pointer (key 149) onto the sleeve (key 101). Turn the handwheel until the pointer is around 20mm below the yoke upper flange. In this location the sleeve will not interfere with the stem connector during the stroking of the actuator. Align the neutral position indicator (key 108) with the pointer.
14. Mount the actuator and handwheel assembly in accordance with the procedures in the Installation section.
15. Mount the actuator on the valve following the procedures in the Installation section.

Side-Mounted Handwheel for Size 2 Actuator

A side-mounted handwheel (figure 12) is normally used as a manual actuator. The power screws (keys 103 and 105) and stem nut (key 104) can be mounted in either of two position orientations so that, regardless of valve plug action, counter-clockwise rotation always opens the valve.

NOTICE

Automatic operation is possible only when the side-mounted handwheel is in the neutral position.

To avoid damage to actuator parts, release all pressure from the casings before using the side-mounted handwheel.

Travel stop, if any installed on the actuator, will not limit the travel when the side-mounted handwheel is operated.

Instructions are given below for complete disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then begin the assembly at the appropriate step.

It may be necessary to apply a temporary loading pressure to the actuator during the disassembly. Key numbers are shown in figure 12.

Disassembly for Side 2 Side-Mounted Handwheel

1. Complete steps 1 through 5 of the disassembly portion of the Actuator Maintenance section.
2. Unscrew the protective cover cap screws (key 134), remove the washers (key 133) and the protective covers (key 107).
3. Unscrew the locknuts (key 132) of the neutral indicator (key 108). Unscrew the cap screws (key 131) of the anti-rotation plate (key 150). Separate the stem connector (key 124) by unscrewing the two stem connector cap screws.
4. If necessary, separate the actuator from the handwheel assembly by removing the cap screws (key 125) and lift off the actuator.

5. Turn clockwise the handwheel to unscrew the upper power screw (key 103 or 105).
6. Remove the lower power screw (key 103 or 105) and stem nut (key 104).
7. If necessary, separate the actuator yoke (key 1) from the handwheel assembly by removing the cap screws (key 24).
8. Remove the handwheel and drive shaft assembly (keys 121 and 109) by unscrewing the cap screws (key 137).
9. If required, the drive shaft assembly can be broken down by removing the nut (key 140), the washer (key 139), the rotation indicator (key 155), the handwheel (key 121), and the worm shaft (key 116) and the bearings and bushings (keys 117 and 118). If required, remove the cap screws and nuts (keys 135 and 136) of the anti-rotator clamped on the drive shaft housing, the anti-rotator (key 153), the spacer (154) and the two clamps (key 152).
10. Remove the worm gear (key 112), the key (key 111), the bearing (key 113) and if required remove the bushing (key 114) from the handwheel yoke (key 106).

Assembly for Size 2 Side-Mounted Handwheel

1. If the drive shaft assembly was separated, coat the bushings (key 118) with lithium grease (key 50) and slide them into the gear case (key 109). Coat the bearings (key 117) and the worm shaft (key 116) with lithium grease (key 50). Place the bearing, insert the worm shaft into the gear case (key 109) and place the second bearing. Install the handwheel (key 121), the rotation indicator (key 155), the washer (key 139) and tighten the nut (key 140). Place the two clamps (key 152), the spacer and the anti-rotator (keys 153 and 154), insert the cap screws and nuts (keys 135 and 136) and tighten.
2. If bushing (key 114) was removed, coat it with lithium grease (key 50) and slide it into the handwheel yoke (key 106).
3. Coat the bearing (key 113), the key (key 111) and the worm gear (key 112) with lithium grease (key 50). Install the key in the worm gear. Place the bearing and slide the worm gear in the handwheel yoke (key 106).
4. If used, apply thread lock (key 52) to the threads of the screw(s) (key 156) and tighten into the power screw(s) (key 103 and/or 105). Coat the threads of the power screws (keys 103 and 105) with lithium grease (key 50). Slide the anti-rotation plate (key 151) onto the lower power screw. Screw the lower power screw into the stem nut (key 104) until the threads of the power screw are fully engaged. Slide the assembly into the worm gear (key 112) with the slot aligned with the key (key 111). Slide the anti-rotation plate (key 150) onto the upper power screw and screw the upper power screw into the stem nut (key 104) until the threads of the power screw are fully engaged.
5. If the actuator yoke (key 1) was removed, slide the neutral indicator (key 108) in the actuator yoke, install the handwheel yoke (key 106) on the actuator yoke, insert the cap screws (key 24) and tighten to the appropriate torque as shown in table 2.
6. If the actuator was separated from the handwheel yoke (key 106), lift the actuator and place it on the handwheel yoke, insert the cap screws (key 125) and tighten to the appropriate torque as shown in table 2.
7. Place the stem connector (key 124) half with the threaded hole fully engaged onto the actuator stem (key 6) and onto the upper power screw (key 103 or 105). Ensure that the anti-rotation plate (key 150) is pointed towards the neutral indicator (key 108) and ensure that the holes in the anti-rotation plate are aligned with the tapped holes on the bottom of the stem connector half.
8. Install the other half of the stem connector and insert the cap screws and tighten them while ensuring even spacing between the stem connector halves on all sides. Install the 4 cap screws (key 131) of the anti-rotation plate and tighten them. Install a nut (key 132) on the neutral indicator (key 106), slide the indicator in the hole of the anti-rotation plate and place the 2 other nuts (key 132).
9. Place the handwheel and drive shaft assembly. Insert the cap screws (keys 137 and 138) and adjust the cap screws (key 138) to eliminate free play between the worm shaft and worm gear. Tighten the cap screws (key 137).

Note

To prevent rotation of the lower power screw during the travel adjustment, before turning the handwheel, assemble the valve stem connector around the lower power screw end the anti-rotating lug on the yoke.

10. Ensure that the 2 power screws have the same threads engagement in the stem nut (key 104), then preventing the rotation of the lower power screw (key 103 or 105) turn the handwheel (key 121) until the 2 power screws are in contact.
11. Perform one of the following procedures (a or b as appropriate):
 - a. For **direct acting actuator**, slightly rotate the handwheel in the opposite direction to have a small gap between the 2 power screws.
 - b. For **reverse acting actuator**, rotate the handwheel in the opposite direction until the lower power screw move down the specified travel and mark the position of the lower power screw. Set the diaphragm loading pressure to approximately 0.5 bar over the upper bench set pressure, release slowly the diaphragm pressure until the actuator stem moves down the specified travel, then rotate the handwheel until the position mark is reached.
12. Align the pointer of the neutral indicator (key 108) with the anti-rotation plate (key 151). Place the protective covers (key 107), the washers (key 133) and tighten the cap screws (key 134).
13. Mount the actuator and handwheel assembly in accordance with the procedures in the Installation section.

Casing-Mounted Adjustable Travel Stops

Casing-mounted adjustable travel stops (shown in figures 13 through 15) are available to limit travel in the down direction (extending the actuator stem) or in the up direction (retracting the actuator stem). The travel stop in figure 13 is a down travel stop, the travel stop in figure 14 is an up and down travel stop, and the travel stop in figure 15 is an up travel stop.

Use the nut (key 206, figures 13 and 14), screw (key 203, figure 14) or cap screw (key 202, figure 15) to set the point at which the travel stop limits travel. Be sure to tighten the locknuts and replace the cap (key 201) after setting the travel stop.

Instructions are given below for disassembly and assembly. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the reassembly at the appropriate step.

It may be necessary to apply a temporary loading pressure to the actuator during the disassembly.

Key numbers are shown in figures 13 through 15.

1. Bypass the control valve, reduce loading pressure to atmospheric, and remove the tubing or piping from the connection in the diaphragm casing(s).
2. Remove the cap (key 201). For reverse acting actuator, ensure that the travel stop in the down direction is not causing any spring compression. For direct acting actuator, ensure that the travel stop in the up direction is not causing any spring compression. If travel stop is causing spring compression, slightly pressurize the actuator diaphragm until movement of the actuator stem is detected and the spring force applied to the travel stop is relieved.
3. For down travel stop (figure 13) and up and down travel stop (figure 14), unscrew the hex nuts (key 205 and 206). For up and down travel stop (figure 14), loosen the locknut (key 204) and unscrew the screw (key 203). For up travel stop (figure 15), loosen the locknut (key 204) and unscrew the cap screw (key 202).
4. Remove the cap screws (key 24) of the protective cap (key 5) and lift off the protective cap.
5. Reassemble parts in the reverse order of removal.
6. Re-adjust the travel stop(s).

Parts Ordering

Each actuator has a serial number stamped on the nameplate. Always mention this number when corresponding with your [Emerson sales office](#) regarding technical information or replacement parts.

WARNING

Use only genuine Fisher replacement parts. Components that are not supplied by Emerson should not, under any circumstances, be used in any Fisher valve, because they may void your warranty, might adversely affect the performance of the valve, and could cause personal injury and property damage.

Parts List

Note

Contact your [Emerson sales office](#) for part numbers.

Figure 1. Fisher 3025 Size P460-200 Actuator

Introduction

Scope of Manual

This instruction manual includes installation, maintenance, and parts information for Fisher 3025 actuators in sizes P460, P462, P460-200, and P900. Refer to separate manuals for instructions covering the positioner and other accessories used with these actuators.

Do not install, operate, or maintain 3025 actuators without being fully trained and qualified in valve, actuator, and accessory installation, operation, and maintenance. To avoid personal injury or property damage, it is important to carefully read, understand, and follow all the contents of this manual, including all safety cautions and warnings. If you have any questions about these instructions, contact your [Emerson sales office](#) before proceeding.

Description

The Fisher 3025 size P460, P462, P460-200 and P900 spring-opposed diaphragm actuators position the valve plug in the valve body in response to varying controller or valve positioner pneumatic output signals applied to the actuator diaphragm. They can be specified either direct (air-to-close) or reverse acting (air-to-open). The size P460 offers 65 mm maximum actuator travel. The sizes P462 and P900 provide 120 mm maximum actuator travel. The size P460-200 offers 203 mm maximum actuator travel. The 3025 actuator can be equipped with a side-mounted assembly. It is usually used as an auxiliary manual actuator.

Table 1. Specifications

SPECIFICATION		ACTUATOR SIZE			
		P460	P462	P460-200	P900
Nominal Effective Area	cm ²	1800	1800	1800	3600

Installation

Key number locations are shown in figures 3 through 12, unless otherwise indicated. Figures 3 and 4 show the size P460 actuator, figures 5 and 6 the size P462, figures 7 and 8 the size P460-200 and figures 9, 10, 11 and 12 illustrate the size P900.

If the actuator is equipped with a side-mounted handwheel, also refer to the figures 13, 14, 15 and 16. Figure 13 shows the size P460 and the size P462 side-mounted handwheel, figure 14 the size P460-200 and figure 15 illustrates the size P900.

⚠ WARNING

To avoid personal injury or parts damage, do not apply operating pressure that exceeds the Maximum Diaphragm Casing Pressure of 4 bar or produces a force on the actuator stem greater than the Maximum Allowable Valve Stem Load. Use pressure-limiting or pressure-relieving devices to prevent the Operating Pressure from exceeding the Maximum Diaphragm Casing Pressure.

- **Valve/Actuator Assembly:** If the actuator and valve are shipped together as a control valve assembly, it has been adjusted at the factory, and may be installed in the pipeline. After installing the valve in the pipeline, refer to the Loading Connection procedures.
- **Actuator Mounting:** If the actuator is shipped separately or the actuator has been removed from the valve, it is necessary to mount the actuator on the valve before placing the valve in the pipeline. Refer to the actuator mounting procedures before placing the valve in service.
- **Positioner:** If a positioner is installed, or is to be installed on the actuator, refer to the positioner instruction manual for installation. During the adjustment procedures, it will be necessary to provide a temporary loading pressure to the actuator diaphragm.

Note

The 3025 diaphragm actuators are designed to mount on push-down-to close valves. Do not mount these actuators on any other type of valve without first contacting your [Emerson sales office](#).

Mounting the Actuator on the Valve

NOTICE

If the valve stem is allowed to remain in the up position (towards the actuator) during mounting, it can interfere with the actuator mounting, possibly damage valve stem threads or bend the valve stem. Be sure the valve stem is pushed down (into the valve body), away from the actuator while mounting.

NOTICE

If the actuator is equipped with a side-mounted handwheel, during mounting it can interfere with the valve stem (even if the valve stem is pushed completely down into the valve body), possibly damage valve stem threads or bend the valve

stem. Be sure the actuator stem is sufficiently retracted (into the side-mounted handwheel), away from the valve while mounting. If not, the actuator stem can be retracted by turning counterclockwise the handwheel. Be sure the actuator stem does not rotate while turning the handwheel (use the anti-rotator to prevent rotation).

1. Provide a vise or some other method of supporting the valve and the weight of the actuator during assembly. Push the valve stem down away from the actuator while mounting the actuator.
2. Lift or hoist the actuator onto the valve bonnet:
 - a. For the 3-9/16 yoke boss: Slowly lower the actuator down onto the valve. As the yoke passes over the end of the valve stem, place the yoke locknut over the valve stem. Once the actuator is in place, screw the yoke locknut onto the valve bonnet and tighten the locknut.
 - b. For all other yoke bosses: Slowly lower the actuator down onto the valve. Once the actuator is in place, insert the cap screws and tighten the hex nuts, securing the actuator to the bonnet.

Travel Stop Adjustment

The actuator is normally shipped adjusted at the factory and you may refer directly to the Installing the Stem Connector Assembly procedures.

If the actuator has been disassembled, it is necessary to adjust the travel stop. You may perform the following procedure before connecting the actuator stem to the valve stem.

WARNING

When moving the actuator stem with loading pressure applied, exercise caution to keep hands and tools out of the actuator stem travel path. If the loading pressure is accidentally disconnected, personal injury and property damage is possible if something is caught between the actuator stem and other control valve parts.

Also provide a certified pressure gauge suitable to accurately read the diaphragm pressure from 0 through the upper bench set pressure marked on the nameplate. Apply loading pressure to the diaphragm.

Stroke the actuator a few times to ensure that the pressure gauge is working correctly, and that the actuator is functioning properly. It is important to be sure that the actuator assembly is not binding or producing any loading friction on the actuator stem movement.

Note

For push-down-to-close valves, the valve plug is the limit for downward travel and the actuator up-stop is the limit for upward travel (away from the valve).

1. If not already accomplished, provide a temporary means of applying adjustable loading pressure to the actuator during the travel stop adjustments.
2. Remove the cap (key 43, figures 3 through 6) or loosen the locknut (key 42, figures 7 through 12). Unscrew the travel stop (key 41).
3. Perform one of the following procedures as appropriate:
 - a. **For an air-to-open actuator:** apply the upper bench set loading pressure to the diaphragm. Adjust the travel stop (key 41) so that it touches the actuator stem. Then lock the travel stop by replacing the cap (key 43) or by tightening the locknut (key 42).

- b. For an air-to-close actuator: apply the lower bench set loading pressure. The actuator should show movement at the lower bench set pressure. Adjust the travel stop (key 41) so that it touches the actuator stem. Then lock the travel stop by replacing the cap (key 43) or tightening the locknut (key 42).
4. Stroke the actuator and check that the actuator is capable of the travel shown on the travel indicator scale (key 74). If the travel span is correct, travel stop adjustment is complete. Proceed to the Installing the Stem Connector Assembly subsection.
5. If the travel span is not correct, a wrong or damaged spring has been installed in the actuator. To obtain the correct spring sizing information, refer to Fisher Catalog 14, Actuator Sizing and Sample Calculations to determine the correct spring selection for your application. Or contact your Emerson sales office for assistance. After replacing the spring, repeat the steps above.

Installing the Stem Connector Assembly

When installing the stem connector assembly, the actuator and valve stem threads should engage the threads of the stem connector by a distance of the diameter of the stem.

1. If necessary, push the valve stem down so that it is touching the seat ring.
2. For an air-to-open actuator only, set the diaphragm loading pressure to approximately 0.5 bar over the upper bench set pressure. The actuator stem should be contacting the upper travel stop.
3. For the size P900 only, screw the actuator and valve stem locknuts away from the connector halves locations.
4. Screw the two stem connectors halves (keys 78 and 79) onto the valve stem and actuator stem. Then place the travel indicator (key 84), the spacer if used (key 86) and the anti-rotator (key 85) on the valve stem connector half.
5. To adjust the travel, perform one of the following procedures as appropriate:
 - a. If the actuator is equipped with a side-mounted handwheel: turn the handwheel so that the distance between the anti-rotator and the actuator stem connector half is equal to the valve travel. Be sure the actuator stem does not rotate while turning the handwheel (use the anti-rotator to prevent rotation). Be sure that the actuator and valve stem threads are engaging the threads of the stem connectors by the distance of at least one diameter of the stem.
 - b. If the actuator is not equipped with a side-mounted handwheel: rotate the connector halves so that the distance between the anti-rotator and the actuator stem connector half is equal to the valve travel. Be sure that the actuator and valve stem threads are engaging the threads of the stem connectors by the distance of at least one diameter of the stem.

NOTICE

Incomplete engagement of the stem connector onto either the valve stem or actuator stem can result in stripped threads or improper operation. Be sure that the length of the actuator stem or the valve stem in the connector is equal or greater than the diameter of that stem. Damage to threads on either stem or in the stem connector can cause the parts to be replaced prematurely.

6. Perform one of the following procedures as appropriate:
 - a. For an air-to-open actuator: Slowly decrease the diaphragm pressure and line up the stem connector halves.
 - b. For an air-to-close actuator: Slowly increase the diaphragm pressure and line up the stem connector halves.
7. Install the cap screws (key 87) with the lock washers if used and tighten them.
8. For sizes P460, P462 and P460-200, install the cap screws (key 80) and the nuts (key 81) and tighten them. For the size P900, screw the valve and actuator stem locknuts against the stem connector halves.

9. Slowly increase and decrease pressure several times, stroking the valve from the lower bench set pressure to the upper pressure.
10. Adjust the travel indicator scale (key 74) to correspond with the travel indicator. Stroke the valve full travel to ensure that the travel matches the valve travel on the travel indicator plate. If travel is not correct repeat the stem connector procedure.
11. If the actuator is equipped with a side-mounted handwheel, insert the screw (key 139) and the nut (key 140) into the stem connector half (key 78). Then screw the nut against the stem connector half. Adjust the handwheel travel indicator (key 113) to correspond with the screw (key 139) used as neutral position indicator. It may be necessary to take off the protective covers (key 119) by removing the cap screws and washers (keys 120 and 128). Once adjusted, replace the protective covers, washers and tighten the screws.

Loading Connection

The loading pressure connections are made at the factory if the valve, actuator, and positioner come as a unit. Keep the length of tubing or piping as short as possible to avoid transmission lag in the control signal. If a volume booster, valve positioner or other accessory is used, be sure that it is properly connected to the actuator. Refer to the positioner instruction manual or other manuals as necessary.

For actuators shipped separately or whenever the actuator pressure connections are installed, use the following steps:

1. Connect the loading pressure piping to the NPT internal connection at the side of the diaphragm casing.
2. Cycle the actuator several times to be sure that the valve stem travel is correct when the correct pressure ranges are applied to the diaphragm.
3. If valve stem travel appears to be incorrect, refer to the travel stop adjustment procedures at the beginning of this section. Do not place the valve in service if it is not reacting correctly to diaphragm loading pressure changes.

Maintenance

Actuator parts are subject to normal wear and must be inspected and replaced when necessary. The frequency of inspection and replacement depends on the severity of service conditions.

WARNING

Avoid personal injury or property damage from sudden release of process pressure or bursting of parts. Before performing any maintenance operations:

- Do not remove the actuator from the valve while the valve is still pressurized.
- Disconnect any operating lines providing air pressure, electric power, or a control signal to the actuator. Be sure the actuator cannot suddenly open or close the valve.
- Use bypass valves or completely shut off the process to isolate the valve from process pressure. Relieve process pressure from both sides of the valve. Drain the process media from both sides of the valve.
- Vent the power actuator loading pressure and relieve any actuator spring precompression.
- Use lock-out procedures to be sure that the above measures stay in effect while you work on the equipment.

When performing maintenance procedures, isolate the control valve from the process line pressure from both sides of the valve. Use the lock-out procedures to be sure that the above measures stay in effect while you are working on the actuator.

Actuator Maintenance

This procedure describes how the actuator can be completely disassembled and assembled. When inspection or repairs are required, disassemble only those parts necessary to accomplish the job; then, start the assembly at the appropriate step.

Key numbers refer to figures 3 through 12 unless otherwise indicated. Figure 3 and 4 show the size P460, figure 5 and 6 the size P462, figure 7 and 8 the size P460-200 and figures 9 through 12 illustrate the size P900.

It may be necessary to apply a temporary loading pressure to the actuator during the disassembly.

Size P460 Actuator

Size P460 Actuator Disassembly

1. Bypass the control valve. Reduce the loading pressure to atmospheric, and remove the tubing or piping from the diaphragm casing (key 1).
2. If the actuator is equipped with a side-mounted handwheel, refer to the Side-Mounted Handwheel Disassembly procedures in the Side-Mounted Handwheel Maintenance section to separate the actuator and handwheel (steps 2 to 7). Then continue the Size P460 Actuator Disassembly procedure from the step 8.
3. For an air-to-open actuator only: slightly pressurize the actuator diaphragm until movement of the actuator stem is detected and the spring force applied to the stem connector is relieved.

⚠ WARNING

To avoid personal injury due to sudden uncontrolled movement of parts, do not loosen yoke locknut or cap screws and do not remove parts of the stem connector when the stem connector has spring force applied to it.

4. Remove the stem connector cap screws (key 87), the anti-rotator (key 85), the spacer if used (key 86) and the travel scale indicator (key 84). Loosen the stem connector halves cap screws and nuts (keys 80 and 81). Remove the stem connector halves.
5. For an air-to-open actuator only: slowly exhaust the diaphragm pressure.
6. To separate the actuator from the valve body, remove the yoke locknut or the bolts and then lift off the actuator.
7. Remove the yoke cap screws (key 77) and then lift the actuator off the yoke.
8. Remove the lifting lug cap screws (key 44), the lifting lug (key 40) and the gasket (key 71). If required remove the cap (key 43) and the travel stop (key 41).

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the diaphragm casing away from the actuator, carefully remove casing cap screws and nuts (keys 45 and 46) (step 9 below) and then relieve the spring compression by unscrewing the nut (key 16) (step 11 below).

9. Remove all the diaphragm casing cap screws and nuts (keys 45 and 46). If required remove the vent (key 49).
10. Remove the set screws (key 57) and if used the travel stop and locknut (keys 65 and 66).
11. Relieve the spring compression by unscrewing slowly the nut (key 16).
12. Remove the washer (key 53), then lift off the diaphragm casing (key 3).
13. Remove the actuator springs (keys 30 and 31).
14. Lift off the stem and diaphragm plate assembly.
15. Unscrew the travel stop (key 54), remove ring (key 17), the wave washers (key 12), the tube (key 51), the diaphragm plate (key 26), the diaphragm (key 47), the O-ring (key 6), the washers if used (key 64) and the travel stop (key 14). Unbend the tab washer (key 13), remove the retaining ring (key 11) and the two nut halves (key 10).

16. From the diaphragm casing (key 1) remove the retaining ring (key 8), the wiper ring and the seal retainer (keys 4 and 5) and the O-ring (key 6).
17. If required remove the casing bushings (keys 7 and 33), the pins (key 28) from the diaphragm casing and diaphragm plate, the hellicoil (key 58), the travel scale, screw and nuts (keys 74, 75 and 76).

Size P460 Actuator Assembly

1. If removed, coat the bushings (keys 7 and 33) with lithium grease (key 201) and slide them into the diaphragm casings.
2. Place the wiper ring (key 4) into the seal retainer (key 5). Apply lithium grease (key 201) to the O-ring (key 6), the wiper ring and seal retainer assembly and install them into the diaphragm casing (key 1). Then place the retaining ring (key 8).
3. If removed, insert the pins (key 28) into the diaphragm casing (key 3) and diaphragm plate (key 26).
4. If removed, insert the hellicoil (key 58) into the nut (key 16).
5. Coat the threads of the stem (key 9) with anti-seize lubricant (key 202).
6. Apply anti-seize lubricant (key 202) to the internal thread of the two nut halves (key 10). Install the nut halves and the retaining ring (key 11). Place the tab washer (key 13) and bend it on the retaining ring. Slide the travel stop (key 14), the washers if used (key 64), the O-ring (key 6), the diaphragm (key 47), the diaphragm plate (key 26), the tube (key 51), the wave washers (key 12) and the ring (key 17).
7. Coat the internal thread of the travel stop (key 54) with anti-seize lubricant (key 202), screw it onto the stem and tighten until the wave washers are completely compressed.
8. Place this stem assembly into the diaphragm casing (key 1). Take care when pushing the actuator stem through the diaphragm casing so that the threads do not damage the bushing, O-ring or wiper ring.
9. Place the actuator springs (keys 30 and 31).
10. Install the diaphragm casing (key 3) so that the vent and air connections are diametrically opposed. Take care when lowering the casing around the stem so that the thread do not damage the bushing. Apply lithium grease (key 201) to the washer (key 53) and place it.
11. Apply anti-seize lubricant (key 202) on the nut internal thread (key 16) and screw it slowly to compress the springs until the two diaphragm casings touch the diaphragm.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following sequence with a manual torque wrench.

NOTICE

Over-tightening the diaphragm cap screws and nuts (keys 45 and 46) can damage the diaphragm. Do not exceed 16 N•m (12 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

12. Align the diaphragm casings and diaphragm holes. Be sure the vent and air connections on the diaphragm casings are still diametrically opposed. Install the cap screws and nuts (keys 45 and 46). Tighten the diaphragm cap screws and nuts in the following manner.

13. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 8 N•m (6 lbf•ft).
14. Tighten the remaining bolts in a clockwise, crisscross pattern to 8 N•m (6 lbf•ft).
15. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 16 N•m (12 lbf•ft).
16. Tighten the remaining bolts in a clockwise, crisscross pattern to 16 N•m (12 lbf•ft).
17. After the last bolt is tightened to 16 N•m (12 lbf•ft) all of the bolts should be tightened again to 16 N•m (12 lbf•ft) in a circular pattern around the bolt circle.
18. Once completed, no more tightening is recommended.
19. Tighten the set screws (key 57) into the nut (16).
20. If used, place the locknut and travel stop on the stem (keys 65 and 66) and screw the locknut against the travel stop.
21. Place the gasket (71) and the lifting lug cap (40) onto one of the diaphragm casings according to the actuator action (air-to-close: key 1, air-to-open: key 3). Insert the cap screws (key 44) and tighten them.
22. If removed, place the travel stop (key 41) into the lifting lug cap.
23. If the actuator is equipped with a side-mounted handwheel, it is necessary to adjust the actuator travel stop before mounting the actuator onto the side-mounted handwheel. Perform the Travel Stop Adjustment in accordance with the procedures in the Installation section. Then refer to the Side-Mounted Handwheel Assembly procedures in the Side-Mounted Handwheel Maintenance section to complete the actuator assembly (from step 9).
24. Lift the actuator and place it onto the yoke. Insert the cap screws (key 77) and tighten them.
25. If removed, screw the vent (key 49) into the diaphragm casing (key 3).
26. Mount the actuator onto the valve in accordance with the procedures in the Installation section.

Size P462 Actuator

Size P462 Actuator Disassembly

1. Bypass the control valve. Reduce the loading pressure to atmospheric, and remove the tubing or piping from the diaphragm casing (key 1).
2. If the actuator is equipped with a side-mounted handwheel, refer to the Side-Mounted Handwheel Disassembly procedures in the Side-Mounted Handwheel Maintenance section to separate the actuator and handwheel (steps 2 to 7). Then continue the Size P462 Actuator Disassembly procedure from the step 8.
3. For an air-to-open actuator only: slightly pressurize the actuator diaphragm until movement of the actuator stem is detected. The spring force applied to the stem connector is relieved.

⚠ WARNING

To avoid personal injury due to sudden uncontrolled movement of parts, do not loosen yoke locknut or cap screws and do not remove parts of the stem connector when the stem connector has spring force applied to it.

4. Remove the stem connector cap screws (key 87), the anti-rotator (key 85), the spacer if used (key 86) and the travel scale indicator (key 84). Loosen the stem connector halves cap screws and nuts (keys 80 and 81). Remove the stem connector halves.
5. For an air-to-open actuator only: slowly exhaust the diaphragm pressure.
6. To separate the actuator from the valve body, remove the yoke locknut or the bolts and then lift off the actuator.
7. Remove the yoke cap screws (key 77), then lift the actuator off the yoke.

8. Remove the lifting lug cap screws (key 44), the lifting lug (key 40), the gasket (key 71) and the spacer if used (key 67). If required remove the cap (key 43) and the travel stop (key 41).
9. Unscrew the cap screws (key 36) and remove the flange (key 34) and gasket (key 72).
10. Unbend the ring retaining (key 59) and slide towards the casing. Remove the 2 ring halves (key 61) and then the ring retaining.

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the diaphragm casing away from the actuator, relieve the spring compression (step 11 below) and carefully remove casing cap screws and nuts (keys 45 and 46) (step 12 below)

11. Relieve the spring compression by unscrewing alternately and slowly the four cap screws (key 32).
12. Remove all the diaphragm casing cap screws and nuts (keys 45 and 46). If required remove the vent (key 49).
13. Lift off the diaphragm casing (key 3).
14. Remove the spring seat (key 29) and actuator spring (key 30).
15. Lift off the stem and diaphragm plate assembly.
16. Unscrew the set screw (key 57) and remove the travel stop (key 52). Loosen the nut (key 10). Remove the ring retaining (key 11), the wave washers (key 12), the tube (key 51), the diaphragm plate (key 26), the diaphragm (key 47), the O-ring (key 6), the travel stop (key 14), the ring retaining (key 60) and the 2 ring halves.
17. From the diaphragm casing (key 1) remove the retaining ring (key 8), the wiper ring and the seal retainer (keys 4 and 5) and the O-ring (key 6).
18. If required, remove the casing bushings (keys 7 and 33), the pins (key 28) from the diaphragm plate and spring seat, thread the travel stop if used (key 66) out of the stem. If required, remove the travel scale, the screws and nuts (keys 74, 75 and 76).

Size P462 Actuator Assembly

1. If removed, coat the bushings (keys 7 and 33) with lithium grease (key 201) and slide them into the diaphragm casings.
2. Place the wiper ring (key 4) into the seal retainer (key 5). Apply lithium grease (key 201) to the O-ring (key 6), the wiper ring and seal retainer assembly and install them into the diaphragm casing (key 1). Then place the retaining ring (key 8).
3. If removed, insert the pins (key 28) into the spring seat (key 29) and diaphragm plate (key 26).
4. Coat the threads of the stem (key 9) with anti-seize lubricant (key 202).
5. Place the two ring halves (key 61) and the retaining ring (key 60). Slide the travel stop (key 14), the O-ring (key 6), the diaphragm (key 47), the diaphragm plate (key 26), the tube (key 51), the wave washers (key 12) and the retaining ring (key 11).
6. Coat the internal thread of the 2 nut halves (key 10) with anti-seize lubricant (key 202) and tighten them until the wave washers are completely compressed.
7. Slide the travel stop (key 52) and tighten the set screw (key 57).
8. Place this stem assembly into the diaphragm casing (key 1). Take care when pushing the actuator stem through the diaphragm casing so that the threads do not damage the bushing, O-ring or wiper ring.
9. Place the actuator spring (key 30). Apply anti-seize lubricant (key 202) into the four cap screw beds of the spring seat. Place the spring seat (key 29) so that the cap screw beds will be aligned with the internal threads of the diaphragm casing (key 3).

10. Install the diaphragm casing (key 3) so that the vent and air connection are diametrically opposed. Take care when lowering the casing around the stem so that the threads do not damage the bushing.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following sequence with a manual torque wrench.

NOTICE

Over-tightening the diaphragm cap screws and nuts (keys 45 and 46) can damage the diaphragm. Do not exceed 16 N•m (12 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

11. Align the diaphragm casings and diaphragm holes. Be sure the vent and air connection on the diaphragm casings are still diametrically opposed. Install the cap screws and nuts (keys 45 and 46). Tighten the diaphragm cap screws and nuts in the following manner.
12. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 8 N•m (6 lbf•ft).
13. Tighten the remaining bolts in a clockwise, crisscross pattern to 8 N•m (6 lbf•ft).
14. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 16 N•m (12 lbf•ft).
15. Tighten the remaining bolts in a clockwise, crisscross pattern to 16 N•m (12 lbf•ft).
16. After the last bolt is tightened to 16 N•m (12 lbf•ft) all of the bolts should be tightened again to 16 N•m (12 lbf•ft) in a circular pattern around the bolt circle.
17. Once completed, no more tightening is recommended.
18. Coat the thread of the four cap screws (key 32) and the internal threads of the diaphragm casing (key 3) with anti-seize lubricant (key 202). Be sure that the cap screw beds into the spring seat are still aligned with the internal threads of the diaphragm casing. Then install and screw alternately and slowly the four cap screws to compress the spring.
19. Place the retaining ring (key 59) onto the stem. Install the ring (key 61) and slide the retaining ring and bend it on the ring.
20. Place the gasket (key 72) and the flange (key 34). Insert the cap screws (key 36) and tighten them.
21. If used, screw travel stop on the stem (keys 66).
22. Place the spacer if used (key 67), the gasket (key 71) and the lifting lug cap (key 40) onto one of the diaphragm casings according to the actuator action (air-to-close: key 1, air-to-open: key 3). Insert the cap screws (key 44) and tighten them.
23. If removed, place the travel stop (key 41) into the lifting lug cap.
24. If the actuator is equipped with a side-mounted handwheel, it is necessary to adjust the actuator travel stop before mounting the actuator onto the side-mounted handwheel. Perform the Travel Stop Adjustment in accordance with the procedures in the Installation section. Then refer to the Side-Mounted Handwheel Assembly procedures in the Side-Mounted Handwheel Maintenance section to complete the actuator assembly (from step 9).

25. Lift the actuator and place it onto the yoke. Insert the cap screws (key 77) and tighten them.
26. If removed, screw the vent (key 49) into the diaphragm casing (key 3).
27. Mount the actuator onto the valve in accordance with the procedures in the Installation section.

Size P460-200 Actuator

Size P460-200 Actuator Disassembly

1. Bypass the control valve. Reduce the loading pressure to atmospheric, and remove the tubing or piping from the diaphragm casing (key 1).
2. If the actuator is equipped with a side-mounted handwheel, refer to the Side-Mounted Handwheel Disassembly procedures in the Side-Mounted Handwheel Maintenance section to separate the actuator and handwheel (steps 2 to 7). Then continue the Size P460-200 Actuator Disassembly procedure from the step 8.
3. For an air-to-open actuator only: slightly pressurize the actuator diaphragm until movement of the actuator stem is detected. The spring force applied to the stem connector is relieved.

⚠ WARNING

To avoid personal injury due to sudden uncontrolled movement of parts, do not loosen yoke locknut or cap screws and do not remove the parts of the stem connector when the stem connector has spring force applied to it.

4. Remove the stem connector cap screws (key 87), the anti-rotator (key 85), the spacer if used (key 86) and the travel scale indicator (key 84). Loosen the stem connector halves cap screws and nuts (keys 80 and 81). Remove the stem connector halves.
5. For an air-to-open actuator only: slowly exhaust the diaphragm pressure.
6. To separate the actuator from the valve body, remove the yoke locknut or the bolts and then lift off the actuator.
7. Remove the yoke cap screws (key 77), then lift the actuator off the yoke.
8. Remove the bellows (key 68). Remove the lifting lug cap screws (key 44), the lifting lug (key 40) and the gasket (key 71). If required, loosen the locknut (key 42) and remove the travel stop (key 41).

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the diaphragm casing away from the actuator, carefully remove casing cap screws and nuts (keys 45 and 46) (step 9 below) and then relieve the spring compression by unscrewing the nut (key 16) (step 11 below).

9. Remove all the diaphragm casing cap screws and nuts (keys 45 and 46). If required remove the vent (key 49).
10. Unscrew the locknut (key 62).
11. Relieve the spring compression by unscrewing slowly the nut (key 16).
12. Remove the washer (key 53), then lift off the diaphragm casing (key 3).
13. Remove the actuator springs (keys 30 and 31).
14. Lift off the stem and diaphragm plate assembly.
15. Unscrew the travel stop (key 54), remove the wave washers (key 12), the tube (key 51), the O-ring (key 6), the diaphragm and diaphragm plate assembly (keys 24, 25, 26 and 47). Remove the retaining ring (key 11) and the two nut halves (key 10).

16. Unscrew the cap screws (key 25), disassemble the ring (key 24), the diaphragm (key 47) and the diaphragm plate (key 26).
17. Unscrew the cap screws (key 70), remove the wiper ring and the seal retainer (key 4 and 5) and the O-ring (key 6).
18. If required, remove the casing bushings (keys 7 and 33) and the pins (key 28) from the diaphragm plate and casing. If required, remove the travel scale, screw and nuts (keys 74, 75 and 76).

Size P460-200 Actuator Assembly

1. If removed, coat the bushings (keys 7 and 33) with lithium grease (key 201) and slide them into the diaphragm casings.
2. Place the wiper ring (key 4) into the seal retainer (key 5). Apply lithium grease (key 201) to the O-ring (key 6), the wiper ring and seal retainer assembly and install them into the diaphragm casing (key 1). Then insert the cap screws (key 70) and tighten them.
3. If removed, insert the pins (key 28) into the diaphragm casing (key 3) and diaphragm plate (key 26).
4. Place the diaphragm (key 47) on the diaphragm plate (key 26). Install the ring (key 24) and the cap screws (key 25) and tighten them.
5. Coat the threads of the stem (key 9) with anti-seize lubricant (key 202).
6. Apply anti-seize lubricant (key 202) to the internal thread of the two nut halves (key 10). Install the nut halves and the retaining ring (key 11). Slide the diaphragm and diaphragm plate assembly (keys 24, 25, 26 and 47), the O-ring (key 6), the tube (key 51), the wave washers (key 12).
7. Coat the internal thread of the travel stop (key 54) with anti-seize lubricant (key 202), screw it onto the stem and tighten until the wave washers are completely compressed.
8. Place this stem assembly into the diaphragm casing (key 1). Take care when pushing the actuator stem through the diaphragm casing so that the threads do not damage the bushing, O-ring or wiper ring.
9. Place the actuator springs (key 30 and 31).
10. Install the diaphragm casing (key 3) so that the vent and air connection are diametrically opposed. Take care when lowering the casing around the stem so that the thread do not damage the bushing. Apply lithium grease to the washer (key 53) and place it.
11. Apply anti-seize lubricant (key 202) on the nut internal thread (key 16) and screw it slowly to compress the springs.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following sequence with a manual torque wrench.

NOTICE

Over-tightening the diaphragm cap screws and nuts (keys 45 and 46) can damage the diaphragm. Do not exceed 16 N•m (12 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

12. Align the diaphragm casings and diaphragm holes. Be sure the vent and air connection on the diaphragm casings are still diametrically opposed. Install the cap screws and nuts (keys 45 and 46). Tighten the diaphragm cap screws and nuts in the following manner.

13. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 8 N•m (6 lbf•ft).
14. Tighten the remaining bolts in a clockwise, crisscross pattern to 8 N•m (6 lbf•ft).
15. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 16 N•m (12 lbf•ft).
16. Tighten the remaining bolts in a clockwise, crisscross pattern to 16 N•m (12 lbf•ft).
17. After the last bolt is tightened to 16 N•m (12 lbf•ft) all of the bolts should be tightened again to 16 N•m (12 lbf•ft) in a circular pattern around the bolt circle.
18. Once completed, no more tightening is recommended.
19. Screw the locknut (key 62) against the nut (key 16).
20. Place the bellows (key 68 and 69).
21. Place the gasket (key 71) and the lifting lug cap (key 40) onto one of the diaphragm casings according to the actuator action (air-to-close: key 1, air-to-open: key 3). Coat the cap screws (key 44) with lithium grease and tighten them.
22. If removed, place the travel stop and the locknut (keys 41 and 42) into the lifting lug cap.
23. If the actuator is equipped with a side-mounted handwheel, it is necessary to adjust the actuator travel stop before mounting the actuator onto the side-mounted handwheel. Perform the Travel Stop Adjustment in accordance with the procedures in the Installation section. Then refer to the Side-Mounted Handwheel Assembly procedures in the Side-Mounted Handwheel Maintenance section to complete the actuator assembly (from step 9).
24. Lift the actuator and place it onto the yoke. Insert the cap screws (key 77) and tighten them.
25. If removed, screw the vent (key 49) into the diaphragm casing (key 3).
26. Mount the actuator onto the valve in accordance with the procedures in the Installation section.

Size P900 Actuator

Size P900 Actuator Disassembly

1. Bypass the control valve. Reduce the loading pressure to atmospheric, and remove the tubing or piping from the diaphragm casings (key 1).
2. If the actuator is equipped with a side-mounted handwheel, refer to the Side-Mounted Handwheel Disassembly procedures in the Side-Mounted Handwheel Maintenance section to separate the actuator and handwheel (steps 2 to 7). Then continue the Size P900 Actuator Disassembly procedure from the step 8.
3. **For an air-to-open actuator only:** slightly pressurize the actuator diaphragm until movement of the actuator stem is detected. The spring force applied to the stem connector is relieved.

WARNING

To avoid personal injury due to sudden uncontrolled movement of parts, do not loosen yoke cap screws and do not remove the parts of the stem connector when the stem connector has spring force applied to it.

4. Remove the stem connector cap screws (key 87), the anti-rotator (key 85) and the spacer if used (key 86). Loosen the stem connector halves locknuts (keys 82 and 83). Remove the stem connector halves.
5. **For an air-to-open actuator only:** slowly exhaust the diaphragm pressure.
6. To separate the actuator from the valve body, remove the yoke locknut or the bolts and then lift off the actuator.
7. Remove the yoke-to-actuator cap screws (key 77), then lift the actuator off the yoke.
8. Remove the lifting lug cap screws (key 44), the lifting lug (key 40) and the gasket (key 71). If required, loosen the locknut (key 42) and remove the travel stop (key 41).

9. Unscrew the cap screws (key 35) and remove the flange (key 34) and gasket (key 72).
10. Unbend the ring retaining (key 59) and slide towards the casing. Remove the 2 ring halves (key 61) and then the ring retaining.

⚠ WARNING

To avoid personal injury from the precompressed spring force thrusting the diaphragm casing away from the actuator, relieve the spring compression (step 11 below) and carefully remove casing cap screws and nuts (keys 45 and 46) (steps 12 and 16 below).

11. Relieve the spring compression by unscrewing alternately and slowly the three cap screws (key 32).

Note

The size P900 is a double stacked diaphragm casings actuator. First disassemble the stack composed of two short diaphragm casings (keys 1 and 2). Then disassemble the stack made of one short and one long diaphragm casings (keys 1 and 3).

12. Remove all the cap screws and nuts (keys 45 and 46) of the short diaphragm casings assembly (keys 1 and 2). If required, remove the vent (key 49).
13. Lift off the diaphragm casing (key 1).
14. Unscrew the nut (key 10). Remove the ring retaining (key 11), the washer (key 55), the O-ring (key 20), the diaphragm (key 48), the diaphragm plate (key 27), the lock washer (key 50), the ring retaining (key 11) and the two nut halves (key 10).
15. Remove the cap screws, the washers (keys 22 and 23) and the diaphragm casing (key 2).
16. Remove all the cap screws and nuts (keys 45 and 46) of the long diaphragm casings assembly (keys 1 and 3). If required, remove the vent (key 49).
17. Lift off the diaphragm casing (key 3).
18. Remove the spring seat with the discs (keys 29 and 39) and actuator spring (key 30).
19. Lift off the stem and diaphragm plate assembly.
20. Unscrew the set screw (key 57) and remove the travel stop (key 52). Loosen the nut (key 10). Remove the ring retaining (key 11), the wave washer (key 50), the tube if used (key 51), the diaphragm plate and diaphragm assembly (keys 24, 25, 26 and 47), the O-ring (key 6), the travel stop assembly (keys 14, 15, 18 and 19), the retaining (key 11) and the two nut halves (key 10).
21. Unscrew the cap screws (key 25), disassemble the ring (key 24), the diaphragm (key 47) and the diaphragm plate (key 26).
22. If required, remove the cap screws (key 18), lock washers (key 19) and disassemble the travel stop (keys 14 and 15).
23. Unscrew the cap screws (key 21), remove the wiper ring and the seal retainer (keys 4 and 5) and the O-ring (key 6).
24. If required, remove the casing bushings (keys 7 and 33), the pins (key 28) from the diaphragm plate and spring seat. If required, remove the travel scale, the screws and nuts (keys 74, 75 and 76).

Size P900 Actuator Assembly

1. If removed, coat the bushing (keys 7 and 33) with lithium grease (key 201) and slide them into the diaphragm casings.
2. Place the wiper rings (key 4) into the seal retainers (key 5). Apply lithium grease (key 201) to the O-rings (key 6), the wiper ring and seal retainer assemblies and install them into the diaphragm casings (key 1). Then insert the cap screws (key 21) and tighten them.

3. If removed, insert the pins (key 28) into the spring seat (key 29) and diaphragm plate (key 26).
4. Assemble the two travel stop parts (keys 14 and 15), install the lock washers (key 18) and the cap screws (key 18) and tighten them.
5. Place the diaphragm (key 47) on the diaphragm plate (key 26). Install the ring (key 24) and the cap screws (key 25) and tighten them.

Note

The size P900 is a double stacked diaphragm casings actuator. First assemble the stack made of a short and a long diaphragm casing (keys 1 and 3). Then mount the stack composed of two short diaphragm casings (keys 1 and 2).

6. Coat the threads of the stem (key 9) with anti-seize lubricant (key 202).
7. Apply anti-seize lubricant (key 202) to the internal thread of the two nut halves (key 10). Install the nut halves and the retaining ring (key 11). Slide the travel stop assembly (keys 14, 15, 18 and 19), the O-ring (key 6), the diaphragm plate assembly (keys 24, 25, 26 and 47), the tube if used (key 51), the lock washer (key 50) and the ring (key 11).
8. Coat the internal thread of the two nut halves (key 10) with anti-seize lubricant (key 202) and tighten them until the lock washer is completely compressed.
9. Slide the travel stop (key 52) and tighten the set screws (key 57).
10. Place this stem assembly into the diaphragm casing (key 1). Take care when pushing the actuator stem through the diaphragm casing so that the threads do not damage the bushing, O-ring or wiper ring.
11. Install the actuator springs (key 30 and 31). Apply anti-seize lubricant (key 202) into the three cap screw beds of the spring seat. Coat the disc (key 39) with anti-seize lubricant (key 202). Install the discs into the spring seat and place the spring seat so that the cap screw beds will be aligned with the internal threads of the diaphragm casing (key 3).
12. Install the diaphragm casing (key 3) so that the vent and air connection are diametrically opposed. Take care when lowering the casing around the stem so that the threads do not damage the bushing.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following sequence with a manual torque wrench.

NOTICE

Over-tightening the diaphragm cap screws and nuts (keys 45 and 46) can damage the diaphragm. Do not exceed 16 N•m (12 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

13. Align the diaphragm casings and diaphragm holes. Be sure the vent and air connection on the diaphragm casings are still diametrically opposed. Install the cap screws and nuts (keys 45 and 46). Tighten the diaphragm cap screws and nuts in the following manner.

14. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 8 N•m (6 lbf•ft).
15. Tighten the remaining bolts in a clockwise, crisscross pattern to 8 N•m (6 lbf•ft).
16. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 16 N•m (12 lbf•ft).
17. Tighten the remaining bolts in a clockwise, crisscross pattern to 16 N•m (12 lbf•ft).
18. After the last bolt is tightened to 16 N•m (12 lbf•ft) all of the bolts should be tightened again to 16 N•m (12 lbf•ft) in a circular pattern around the bolt circle.
19. Once completed, no more tightening is recommended.
20. Coat the thread of three cap screws (key 32) and the internal threads of the diaphragm casing (key 3) with anti-seize lubricant (key 202). Be sure that the cap crew beds into the spring seat are still aligned with the internal threads of the diaphragm casing. Then install and screw alternately and slowly the three cap screws to compress the springs.
21. Place the retaining ring (key 59) onto the stem. Install the ring (key 61) and slide the retaining ring and bend it on the ring.
22. Place the gasket (key 72) and the flange (key 34). Insert the cap screws (key 34) and tighten them.
23. Place the diaphragm casing (key 2) so that the vent connection is diametrically opposed to the air connection of the diaphragm casing (key 1) next to. Install the lock washers (key 23) and the cap screws (key 22) and tighten them.
24. Apply anti-seize lubricant (key 202) to the internal thread of the two nut halves (key 10). Install the nut halves and the retaining ring (key 11). Slide the lock washer (key 50), the diaphragm plate (key 27), the diaphragm (key 48), the O-ring (key 20), the washer (key 55), the retaining ring (key 11).
25. Coat the internal thread of the two nut halves (key 10) with anti-seize lubricant (key 202) and tighten them until the lock washer is completely compressed.
26. Place the diaphragm casing (key 1) so that the vent and air connection are diametrically opposed. Take care when sliding the diaphragm casing around the stem so that the threads do not damage the bushing, O-ring or wiper ring.

Note

When you replace actuator diaphragms in the field, take care to ensure the diaphragm casing bolts are tightened to the proper load to prevent leakage, but not crush the material. Perform the following sequence with a manual torque wrench.

NOTICE

Over-tightening the diaphragm cap screws and nuts (keys 45 and 46) can damage the diaphragm. Do not exceed 16 N•m (12 lbf•ft) torque.

Note

Do not use lubricant on these bolts and nuts. Fasteners must be clean and dry.

27. Align the diaphragm casings and diaphragm holes. Be sure the vent and air connection on the diaphragm casings are still diametrically opposed. Install the cap screws and nuts (keys 45 and 46). Tighten the diaphragm cap screws and nuts in the following manner.
28. The first four bolts tightened should be diametrically opposed and 90 degrees apart. Tighten these four bolts to 8 N•m (6 lbf•ft).

29. Tighten the remaining bolts in a clockwise, crisscross pattern to 8 N•m (6 lbf•ft).
30. Repeat this procedure by tightening four bolts, diametrically opposed and 90 degrees apart, to a torque of 16 N•m (12 lbf•ft).
31. Tighten the remaining bolts in a clockwise, crisscross pattern to 16 N•m (12 lbf•ft).
32. After the last bolt is tightened to 16 N•m (12 lbf•ft) all of the bolts should be tightened again to 16 N•m (12 lbf•ft) in a circular pattern around the bolt circle.
33. Once completed, no more tightening is recommended.
34. Place the gasket (71) and the lifting lug cap (40) onto one of the diaphragm casings according to the actuator action (air-to-close: key 1, air-to-open: key 3). Insert the cap screws (key 44) and tighten them.
35. If removed, place the travel stop and the lock nut (keys 41 and 42) into the lifting lug cap.
36. If the actuator is equipped with a side-mounted handwheel, it is necessary to adjust the actuator travel stop before mounting the actuator onto the side-mounted handwheel. Perform the Travel Stop Adjustment in accordance with the procedures in the Installation section. Then refer to the Side-Mounted Handwheel Assembly procedures in the Side-Mounted Handwheel Maintenance section to complete the actuator assembly (from step 9).
37. Lift the actuator and place it onto the yoke. Insert the cap screws (key 77) and tighten them.
38. If removed, screw the vents (key 49) into the diaphragm casings (keys 2 and 3).
39. Mount the actuator onto the valve in accordance with the procedures in the Installation section.

Side-Mounted Handwheel Maintenance

Instructions are given below for complete disassembly and assembly of a side-mounted handwheel. Perform the disassembly only as far as necessary to accomplish the required maintenance; then, begin the assembly at the appropriate step.

If it is only necessary to separate the actuator from the side-mounted handwheel, perform the eight first steps of the following Side-Mounted Handwheel Disassembly procedure. Then to mount the actuator on the side-mounted handwheel begin at the step 9 of the Side-Mounted Handwheel Assembly procedure.

Key numbers refer to figures 13, 14, 15 and 16 unless otherwise indicated. Figure 13 shows the sizes P460 and P462 Handwheel, figure 14 the size P900, figure 15 the size P460-200 and figure 16 illustrates the driving shaft assembly.

It may be necessary to apply a temporary loading pressure to the actuator during the assembly.

Side-Mounted Handwheel Disassembly

1. Bypass the control valve. Reduce the actuator loading pressure to atmospheric, and remove the tubing or piping from the diaphragm casing.
2. For an air-to-open actuator only: Turn counterclockwise until movement of the handwheel stem is detected. The spring force applied to the stem connector is relieved.

⚠ WARNING

To avoid personal injury due to sudden uncontrolled movement of parts, do not loosen yoke cap screws and do not remove the parts of the stem connector when the stem connector has spring force applied to it.

Figure 2. Side Mounted Handwheel

3. Remove the stem connector cap screws (key 87), the anti-rotator (key 78), the spacer if used (key 86) and the travel scale indicator (key 85). For the sizes P460, P462 and P460-200, loosen stem connector halves cap screws and nuts (keys 80 and 81) and unscrew the connector halves. For the size P900, unscrew the stem connector locknuts (keys 82 and 83) and then the connector halves.
4. To separate the actuator from the valve body, remove the yoke locknut or the bolts and then lift off the actuator.
5. For the sizes P460, P462 and P900 remove the cap screws (key 122). For the size P460-200 remove the bolts (keys 122 and 132). Then lift the actuator and handwheel assembly off the yoke.
6. Unscrew the protective cover cap screws (key 120), remove the washers (key 128) and the protective covers (key 119).
7. Remove the stem connector cap screws (key 125 or 137). For the sizes P460 and P462, loosen the stem connector cap screws and nuts (keys 130 and 131) and unscrew the connector half. For the sizes P900 and P460-200, unscrew the stem connector locknut (key 136) and then the connector half (key 124).
8. Remove the cap screws (key 77), then lift the actuator off the handwheel.

Note

To disassemble the actuator, refer to the Actuator Disassembly procedures in the Actuator Maintenance section (from step 8). Following steps describe only how the side-mounted handwheel can be completely disassembled.

9. Remove the travel scale indicator (key 113) by loosening the cap screw that maintain it or for the size P460-200 by unscrewing the two nuts (key 129).
10. For the size P460-200, remove the two bellows (keys 133, 134 and 135).
11. Turn clockwise the handwheel to unscrew the upper threaded shaft (key 111).
12. Remove the lower threaded shaft and shaft connector assembly (keys 109 and 110). Remove the upper threaded shaft and bridge (keys 111 and 112). For the size P460-200, if required disassemble the upper threaded shaft by removing the pin (key 127) and unscrewing the bridge (key 112).
13. Remove the driving shaft assembly (keys 114, 116, 117 and 118) by loosening the cap screws that hold it in place (keys 115 and 126).

14. If required, the driving shaft assembly can be broken down by removing the nut (key 118), the washer (key 117), the rotation indicator (key 114.5), the handwheel (key 116), and then the driving shaft (key 114.4) and the bearing (key 114.3). If required, remove the cap screws and nuts (keys 114.9 and 114.10) of the anti-rotator clamped on the driving shaft housing (key 114.1), the anti-rotator (key 114.7), the spacer (114.8) and the two clamps (key 114.6).
15. Remove the screws (key 108), the washer (key 107), the key (key 106), the gear ring (key 105) and the bearing (key 104). If required, remove the bushing (key 103) from the gear housing (key 102).

Side-Mounted Handwheel Assembly

1. If the driving shaft assembly was separated, coat the bushings (key 114.2), the bearing (key 114.3) and the shaft (key 114.4) with lithium grease (key 201). Place the bearing, and then insert the shaft into the housing (key 114.1). Place the handwheel (key 116), the rotation indicator (key 114.5), the washer (key 117) and then insert and tighten the nut (key 118). Place the two clamps (key 114.6), the spacer and the anti-rotator at the opposite (keys 114.7 and 114.8), insert the cap screws and nuts (key 114.9 and 114.10) and tighten them.
2. If removed, coat the bushing (key 103) with lithium grease (key 201) and slide it into the housing (key 102).
3. Coat the bushing (key 103), the bearing (key 104) and the gear ring (key 105) with lithium grease (key 201). Place the gear housing (key 102) onto the yoke, install the bearing (key 104), and the gear ring (key 105).
4. Coat the thread of the shafts (keys 110 and 111) and the internal threads of the shaft connector (key 109) with anti-seize lubricant (key 202). Insert the lower threaded shaft (key 110) into the shaft connector (key 109) by engaging three or four threads.
5. For the size P460-200, if the upper threaded shaft (key 111) was separated from the bridge (key 112), screw the shaft into the bridge. Align the holes and insert the pin (key 127).
6. Apply lithium grease (key 201) to the inside of the gear ring (key 105). Place the shaft assembly (keys 109 and 110) into the gear ring and align the grooves. Apply lithium grease (key 201) to the key (key 106) and insert it. Place the washer (key 107), insert the screws (key 108) and tighten them.
7. Coat the handwheel assembly cog (key 114) and the gear ring cog (key 105) with anti-seize lubricant (key 202). Place the handwheel assembly. Insert the cap screws (keys 115 and 126) and adjust the gap between the gear cogs by screwing or unscrewing the cap screws. Then tighten the cap screws (key 115).
8. Place the bridge (key 112) and the upper shaft (key 111). Insert the upper shaft into the shaft connector (key 109) by turning counter-clockwise the handwheel. Engage three or four threads as done previously for the lower shaft.

Note
